Don't worry—

A doctor's time is taken up mostly with thinking — he has not (or should not have) one moment to spare for worrying

Thinking develops keenness in intellectual and practical matters. Promotes a fertile mind capable of new ideas. It plans big things and makes a man strong. It is constructive. But as soon as thinking becomes disorganized — worry begins.

Worry, on the other hand, tears down and destroys or weakens. It results from a confused and shuffled mind or body sorely in need of repair. With a calm mind and a sound body, good thinking is easier. Worry is not the result of clear thinking — it is the result of trying to think under the wrong conditions, irrationally and without the right perspective.

The connection between the above and reading advertisements in your copy of this JOURNAL may seem far-fetched, but it doesn't take very much thinking to appreciate that the services and products advertised do play an important part in your every day thinking and hence should not be slighted.

Keeping tabs of advertisers and the things they feature will undoubtedly avert worrying about where to get some certain thing or where to send a patient.

Introducing Our New Ultra-Short Wave Apparatus

This impressive Garfield ULTRA-SHORT WAVE Apparatus, operated by a **SPARK GAP WHICH IS CONSTRUCTED DIFFERENTLY** from any other on the market, contributes beauty and prestige to a Doctor's office.

After months of research and experimentation by experts, the Garfield High Frequency Laboratories, Inc., have developed a Spark Gap which offers the physician a **SURPLUS OF POWER OUTPUT**

THIS GAP IS CONSTRUCTED DIFFERENTLY FROM ANY OTHER ON THE MARKET

Among the many unique features of this most beautiful ULTRA-SHORT WAVE Machine are the following

A RESERVE OF POWER for air spaced electrodes giving specific thermal depth effect.
SMALLEST ELECTRODES may be used as effectively as the largest.

TREATMENT WITH THE INDUCTION COIL CUTTING in which no metal indifferent electrode is required — cuts under water

PERFECT COAGULATION — both bipolar and monopolar

SIMPLIFIED DESICCATION

ARMS may be moved to any angle or position without the tightening of a single knot and are concealed when not in use.

COMPARTMENTS in which all electrodes may be hung and foot-switch and surgical outfit conveniently stored

SLIDING PANELS for treatment of extremities

AUTOMATIC TIMER.

OPTIONAL FINISH.

AN INTRODUCTORY PRICE FAR BELOW ANYONE'S EXPECTATION

Equipped with ball-bearing casters

It was 1924... and there was no tomato juice

"MAKE a tomato juice that I can recommend with confidence," said a physician to the three Kemp brothers in the summer of 1924

In those days the juice of tomatoes was used only in infant feeding—and was NOT available commercially. But Kemp brothers were working on the idea And in 1928—after four years of

research and experimenting—they introduced their product—the now famous Kemp's Sun-Ray Tomato Juice. Made by an exclusive process (U S Pat. No. 1746657), it is the *original* vitamin certified, non-separating, undiluted tomato juice. Packed in enamel-lined cans to prevent "tin taste." . . . Available at all food stores Send for free copy of Steenbock Report J-36 on Feeding Tests The Sun-Ray Co (Div Kemp Bros Packing Co), Frankfort, Ind

IN VOMITING OF INFANTS

KNOX GELATINE

REDUCES MILK CURD TENSION 50%

With gelatine soft flocculent milk curds

Without gelatine hard indigestible milk curds

KNOX
SPARKLING
GELATINE

ONE per cent of Knox Gelatine added to the formula reduces milk curd tension over 50%. The curds instead of being tough and leathery, are emulsified—made softer and finer. This is an obvious advantage in vomiting.

Colloidal Protection—Knox Gelatine has an effective colloidal action. It helps to emulsify ingested fats. Gelatine also serves as a protective agent when combined with fruit juices or with strained and raw foods.

Growth Promotion—Knox Gelatine contains 85% of easily digested and assimilated protein, rich in lysine—a growth-promoting amino acid. Thus, it is a valuable supplement to the protein content of the diet.

Knox Gelatine is made as carefully as an ampule solution, surpassing in all respects the minimum U S P requirements, pH about 6.0, contains no carbohydrates, bacteriologically safe.

Formula for Modification of Milk with Knox Gelatine

Sprinkle two envelopes of Knox Gelatine on 4 ounces of cold water. Allow to soak for ten minutes. Add 6 ounces of boiling water and stir until dissolved. Add 20 ounces of milk and 1½ ounces of carbohydrate.

Send for this new, pertinent booklet. Mail coupon today.

FOR THE UNITED STATES PUBLIC HEALTH SERVICE

This presentation of a uniform type of procedure in the treatment of early syphilis is the product of a genuinely massive investigation of world-wide scope, sponsored by the League of Nations Health Organization and carried through in the United States by the combined efforts of the United States Public Health Service and a group of five university clinics aided by the generosity of several donors. The material embraces the records of 75,000 cases of syphilis, of which 3,244 were examples of early syphilis followed for as long as six months or more. These figures, while themselves impressive, express an aggregate more than any as yet fully evaluated in the history of medicine, and are entirely capable of serving as a basis

Four CAPSULES, T. I. D.

The concentration of antianemic material in Pulvules 'Extralin' (Stomach Concentrate, Lilly) is suggested by comparing these. The raw or cooked liver necessary to equal the blood regenerating effect of the Pulvules 'Extralin' would fill the larger capsule.

Pulvules 'Extralin' afford a method of oral treatment in pernicious anemia which is more agreeable to the patient than the ingestion of raw liver as such. Four pulvules (filled capsules), t. i. d., will produce a satisfactory reticulocyte response in most cases. Pulvules 'Extralin' are effective, tasteless, and convenient.

Supplied through the drug trade in bottles of 84 and 500 pills.

Eli Lilly and Company

INDIANAPOLIS, INDIANA, U. S. A.

A new indication for AMNIOTIN

ON APRIL 25TH, it was reported before St. Louis County Medical Societies that the use of estrogenic substance in 50 women relieved nausea and vomiting of pregnancy

This finding opens a new field of usefulness for Amniotin—a physiologically assayed preparation of estrogenic substance. Amniotin has also been found effective in the treatment of symptoms accompanying the menopause (natural or surgical), gonococcal vaginitis in children, senile vaginitis, functional dysmenorrhea, missed abortion, and adenosis of the breast and painful breast. In three dosage forms—

Amniotin in Oil (for hypodermic use) 10,000 International units per cc., boxes of 6, 25 and 100—1 cc ampuls, 2000 International units per cc., boxes of 6, 25 and 100—1-cc. ampuls

Amniotin Pessaries (vaginal suppositories) 2000 International units per pessary, boxes of 6 pessaries

Amniotin Capsules (for oral use) 1000 International units per capsule, boxes of 20 and 100 capsules

Two other important SQUIBB SEX HORMONE PRODUCTS

Follutein—The anterior pituitary-like factor from pregnancy urine. It is useful in certain types of functional uterine bleeding, and, in the male, in the treatment of undescended testes and azoospermia. Supplied in 1-cc. vials containing 500 rat units and a 4-cc. vial of diluent and in 2-cc. vials containing 1000 rat units and an 8-cc. vial of diluent.

Anterior Pituitary Extract—An alkaline aqueous extract of the anterior pituitary glands of cattle, contains the growth-promoting, thyrotropic and sex-complementary factors. Supplied in 10 cc. vials containing 100 growth units.

Attractive Reception Room Furniture

Modern metal furniture—as produced by Doehler—is excellent for reception rooms and has distinct advantages from an economic viewpoint in addition to its charm and beauty

Clean, flowing lines combine with utmost durability and long life to satisfy the needs of the Doctor whose reception room must be in perfect taste without constant expense for upkeep

Now that modern metal furniture has taken its place in the decorative scheme, its use in reception rooms and offices demonstrates a forward-looking attitude and the readiness to adopt new ideas when their worth is established

Members of the Medical Society of New York State are invited to call and will be allowed the usual professional discounts on furniture for their professional or residential requirements

Doehler, as you undoubtedly know, manufactures a complete line of metal furniture and equipment for hospital private and staff rooms, wards, nurses' stations, operating rooms, etc

KARO

BEFORE AND AFTER OPERATIONS

WATER BALANCE (24 HOURS)	
<i>Intake</i>	<i>Outgo</i>
Drinking Water (600 cc)	Urine (800 cc)
Beverages (600 cc)	Skin (700 cc)
Solid Food (700 cc)	Lungs (600 cc)
Metabolic Water (300 cc)	Feces (100 cc)

SURGEONS prepare patients pre-operatively to prevent acidosis and post-operatively to protect nutrition. Karo serves this dual purpose. Given with a soft diet before operation the patient will better resist surgical acidosis. And Karo forced with fluids after operation provides vital energy the patient craves.

Acidosis accompanies anesthesia and toxicity follows surgical trauma. Their effects may be moderated by the administration of Karo. It enriches the glycogen reserves thereby helping to prevent surgical acidosis, decrease post-anesthetic vomiting, stim-

ulate the strained heart and combat shock.

After operation nutrition wanes when the patient cannot tolerate food. Karo with fluids helps maintain the water balance of the body and tides the patient over with basal energy. Karo provides 60 calories per tablespoon. It is relished added to milk, fruit juices and vegetable waters. Karo is a mixture of dextrans, maltose and dextrose (with a small percentage of sucrose added for flavor), well tolerated, not readily fermentable, and effectively utilized.

Corn Products Consulting Service for Physicians is available for further clinical information regarding Karo. Please Address: Corn Products Sales Company, Dept. NM-9, 17 Battery Place, New York City.

ELI LILLY AND COMPANY

FOUNDED 1876

Makers of Medicinal Products

Ephedrine Relieves Congestion

The local application of ephedrine to mucous membranes causes capillary contraction and reduces swelling. Relief of congestion in upper respiratory passages is prompt and well sustained.

For topical treatment.

Inhalant Ephedrine Compound, Lilly, containing aromatics.

Inhalant Ephedrine, Plain, Lilly, without aromatics.

Solution Ephedrine Sulfate, Lilly, and Solution Ephedrine Hydrochloride, Lilly.

These products and other ephedrine preparations for oral or parenteral use are supplied to the drug trade.

THE ROLE OF THE THYMUS AND PINEAL GLANDS IN GROWTH AND DEVELOPMENTL G ROWNTREE M D J H CLARK, M D ARTHUR STEINBERG N H EINHORN,
M D, *Philadelphia, Pa*, and ADOLPH M HANSON, M D, *Faribault, Minn**From the Philadelphia Institute for Medical Research, the Samuel Bell, Jr Laboratory, in the Philadelphia General Hospital, the Laboratories of the Philadelphia General Hospital, and the Hanson Research Laboratory, Faribault, Minn*

During the past three years we have been conducting certain experiments designed to throw additional light on the functions of the thymus and pineal glands. In each series of experiments the same basic principle has been adhered to, namely, a continuation of the adopted procedure through succeeding generations of rats. This has involved (1) the injection of thymus extract (Hanson), (2) the ablation of the thymus glands, (3) thymectomy, with replacement therapy, by injection of thymus extract, (4) thymectomy, with replacement therapy with thymus implants, (5) frequently repeated homologous thymus implants in normal animals, (6) the effects of radiation on the thymus gland, (7) the injection of pineal extract (Hanson). A brief outline is presented of the effects to date of these various procedures.

1 The Effects of thymus injection For the past three years we have been continuing the daily intraperitoneal injection (1 c.c.) of thymus extract, originally prepared by Hanson, through successive generations of white rats (Wistar strain), and are now in the twelfth generation. During this period there have been 1240 litters born yielding more than 8,000 rats. There resulted accruing acceleration in the rate of growth

and development in succeeding generations. It should be acknowledged that these results were not obtained without temporary setbacks in our experiments, as not infrequently we found that, for one reason or another, we were using inert extracts, which failed to produce the expected acceleration in growth and development. A chemical analysis of the potent and inert extracts showed us that potent extracts were relatively rich in iodine reducing compounds, which we have expressed in terms of glutathion. Unless these extracts were maintained at a relatively low pH (around 3.8-4.2) there was, with the lapse of time, a rather rapid decrease in the content of the glutathion-like substance, until the extract was entirely impotent. Again, extracts prepared at various times in the Institute in exactly the same manner, yielded widely different values for the glutathion-like substance, and also variable biological results. After experimenting these last two years with the preparation of the extracts, we have arrived at a point where we can obtain the best and most constant results by using the neck thymus glands of four weeks' old, locally raised, milk-fed calves, obtained from certain dealers in the central eastern part of Pennsylvania. The final extract is adjusted to a pH of 3.8-4.2, which seems to yield optimal stability. The number of animals now under study necessitates the

This work was supported by a grant from the Penrose Fund of the American Philosophical Society. We wish to acknowledge, with gratitude, the financial assistance given Dr. Hanson by the Josiah Macy, Jr. Foundation. The investigations involving thymectomy, implants in normal animals and pinealectomy were

carried out in collaboration with, and replacement therapy independently by Dr. Einhorn. Part of thesis studies submitted to the Faculty of the Graduate School of Medicine of the University of Pennsylvania, in partial fulfillment of the requirements for the degree of Doctor of Medical Science (ScD Med).

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 29, 1936

CHART I—WEIGHT CURVES OF THYMUS
TREATED RATS WITH THEIR CONTROLS

The control is based on 400 animals, observed over a period of three years. The F_1 , F_2 and F_3 groups are based on several hundred animals each. The curve incorporating F_4 to F_6 represents the combined average for these three generations—based on several hundred animals. The curve incorporating F_7 to F_{11} represents the combined average for these four generations—based on several hundred animals.

preparation of new extract at least once a week, which tends to insure both freshness and potency.

An attempt has been made to assay each batch of thymus extract immediately after its preparation, utilizing the quantitative method of Woodward and Fry for the amount of sulphhydryl. With the same procedure, utilizing different thymus glands, the yield of sulphhydryl has varied from almost zero, in the case of extracts prepared from the glands of starved animals, to ninety-four mg per cent from glands of locally raised, milk-fed calves. This procedure has permitted the rough standardization of the extract and, in addition, the opportunity, through utilizing the test at weekly intervals, for the determination of the rate of its deterioration. As a result it has become evidence that potent extracts preserved in soft glass containers, either with or without refrigeration and with or without chlorbutanol, deteriorate rapidly, so that at least one-half of the potency is lost in the course of a month. Infection of the extract with either bacteria or moulds leads to rapid deterioration and often to putrefaction and the sulphhydryl disappears entirely. These observations are of the greatest significance in explaining the success or failure to obtain consistent biological effects on the rate of growth and development. No biological effect has ever been observed with solutions containing less than fifteen mg per cent.

The exact nature of the active principle present is not known. The possibilities that glutathion, cystein, cystin, and glutamic acid

are concerned are being ascertained through the administration of these amino acids, to successive generations of rats. Mild suggestions of precocity have attended the use of large amounts of glutathion and cystein in an occasional litter. Further work along this line is in progress. In this connection it might be mentioned also that inconstant precocity has been observed in HCl extracts of other lymphoid glands (lymph gland, tonsils, and spleen).

The results of this study have been published from time to time and are summarized in Table I and Chart I. The accruing increase in the acceleration in growth as revealed in the weight curve, is most striking up to the seventh generation and in the processes of development up to the tenth generation. Our data would seem to indicate that the limit in the influence on both growth and development has been attained perhaps, and that little increase beyond the present limits can be expected in the future.

Thymus extract in the growth of teeth
Early eruption and marked increase in the rate of growth of the teeth have been observed and reported by Barrett¹

The effect of thymus extract on myelination Dr A. C. Buckley says

Studies concerning development of the central nervous system reveal rapid advancement of the rate of development, in terms of medullation, in successive generations in treated animals. A six-day tenth generation treated animal shows medullation in the spinal cord approximately equivalent to a twenty-four day normal animal. Medullated nerve fibers have been found in a twenty-four hour old animal, in amounts nearly equal to a three day normal control rat.

2 Thymectomy through successive generations For the past one to one and a half years, a series of rats has been thymectomized in successive generations. We are now in the fifth generation, with results as indicated in Chart II and Table II. From a study of these it is evident that as a result of thymectomy, there is definite retardation in the rate of growth, as indicated by the weight curves and the body length, and also a slight retardation in the rate of development, which does not, however, become evident until the fourth or fifth generation is reached.

3 Replacement therapy with thymus extract in thymectomized rats During the same period of time, replacement therapy has been carried out, using thymus extract.

in the amounts employed in our thymus injection series of rats, (1 cc intraperitoneally daily) The young of each generation are thymectomized at approximately twenty days of age and mated, and the injection of the extract started When the litter cast has reached twenty days of age, pairs are again mated, thymectomized, and thereafter injected with the extract. In the fifth generation, which has now been reached, it is found that the retardation of growth caused by thymectomy, has been more than overcome by the amount of thymus extract used, since the resulting rats indicate a rate of growth and development, in excess of normal (Chart III and Table III)

4 Replacement therapy with homologous thymus implants in thymectomized rats

Thymus implants have been utilized in

CHART III—GROWTH CURVES OF SUCCESSIVE GENERATIONS OF THYMECTOMIZED RATS TREATED WITH THYMUS EXTRACT

CHART IV—GROWTH CURVES OF SUCCESSIVE GENERATIONS OF THYMECTOMIZED RATS RECEIVING HOMOLOGOUS THYMUS IMPLANTS

thymectomized animals in an effort to see whether frequent implants at five days' intervals were capable of overcoming the retardation incident to thymectomy. In this series we have reached the fourth generation. The results of these studies are presented in Chart IV and Table IV, from which it can be seen that the thymus implants have entirely overcome the retardation incident to thymectomy. In fact the implants have resulted in an acceleration of growth and development, so that in the fourth generation of this series, the acceleration in the rate of growth and development is roughly comparable to that observed in the third generation of the thymus injected series.

5 The effects of thymus implants in normal rats * Comparable studies have been carried out in normal animals and implants have been made at five to seven days' intervals in young rats of each generation, starting at twenty-five days of age. Accruing acceleration in the rate of growth and development have been observed in this series, in the fourth generation, almost comparable to that resulting from injection of thymus extract in the third generation (Chart V and Table V)

6 The effects of radiation on the thymus gland in successive generations of rats In conjunction with Drs. Dorrance and Hughes of the Oncologic Hospital, x-ray treatment in moderate dosage has been administered to the thymus gland of newborn rats in two successive generations. In the first generation slight retardation was noted in growth, as reflected in the weight curve. In the second generation the retardation in growth is greater. In this experiment, however, it should be stated that the work is only in its earliest phases and that but few animals have been observed. It should be further noted that though every effort has been made to confine the radiation to the thymus gland itself, it is probable that other structures have also been affected by stray radiation.

7 The effects of pineal extract (Hanson) For the past two years a series of rats have been given daily intraperitoneal injections of pineal extract (Hanson), PB₂ containing 0.21% picric acid. In successive generations of rats this has produced accruing retardation in the rate of growth and accruing acceleration in the rate of development and differentiation. The nature and

* Preliminary study of some of the implants has shown vascularization of the reticular residual tissue with extreme paucity of lymphocytes. They bear very slight resemblance to adult thymic tissue, even after the lapse of weeks. No apparent difference has been noted in the implants of thymectomized animals or those of normals.

extent of these effects can be seen from Chart VI and Table VI. Various modifications of this method of extraction of pineal extract have been employed by Dr. Hanson but without yielding extracts that were so effective.

Realizing that criticism might be expressed over the presence of picric acid in this extract, an aqueous HCl extract has been employed now in our laboratory for approximately a year. We are now in the third generation under treatment, with results analogous in every respect to those obtained with PB₂.

Encouraged by the results of our studies, in which thymectomy in successive generations of rats yielded effects diametrically opposed to those resulting from thymus injections, pinealectomy has been undertaken in a series of animals. These experiments have been followed now for a year and a half, pinealectomy having been performed in rats at about eight days of age. Although we are now in the fourth generation, no constant or significant results have been obtained to date, except that the animals breed somewhat more slowly than in our other groups. Further work along this line is necessary, however, before any definite statement can be made concerning the effects of pinealectomy.

Discussion

From the foregoing it is evident that almost unbelievable changes in the rate of growth and development have been effected in the young by the various procedures discussed. Chart VII is a composite graph of the extreme (last generation thoroughly studied) results of the six experiments outlined, and shows at a glance the accruing acceleration of growth in rats, as indicated by weight, from frequent thymus injections or implants, and the retardation in growth resulting from thymectomy and the administration of pineal extract. Thus from five to thirty days the weight of the thymus treated strain is five times, and for the subsequent thirty days—three times that of the pineal treated group.

The various effects of these same six procedures on somatic development is shown in Table VII. The data cover the most marked effects observed to date and illustrate the accruing acceleration in the rate of development resulting from the administration of thymus extract, and the retardation incident to thymectomy or administration of pineal extract. Thus in the thymectomized rat the eyes may open as

late as nineteen days, whereas in the thymus-treated strain they have opened in forty-two hours.

A study of the Tables and Charts will reveal the accruing nature of the effects of each procedure. Amplification becomes more pronounced with passage through successive generations. It is important to note that results of treatment observed in the late litters of one pair of

CHART V—GROWTH CURVES OF SUCCESSIVE GENERATIONS OF RATS RECEIVING HOMOLOGOUS IMPLANTS OF THE THYMUS GLAND

CHART VI—GROWTH CURVES OF SUCCESSIVE GENERATIONS OF PINEAL-TREATED RATS

parents is insignificant when compared with the results from this amount of treatment when distributed through several generations. This amplification of results in successive generations of animals treated is, so far as we know, something new in biology. The explanation is not evident as yet. It is of interest that treatment of both parents is essential to maximal effect. Treatment of the female alone yields results much less striking, while treatment of the male alone gives little or no effect.

Estrus has been demonstrated repeatedly, by vaginal smears, in the tenth generation, thymus-treated strain at nine to twelve days, in animals weighing less than thirty grams. The mature follicles likewise have been demonstrated grossly under the same conditions. Teeth have been observed and demonstrated in the first day of life in animals weighing under six grams. Likewise, in our pineal-treated strain, the teeth have erupted in two days and the eyes opened in five days, in animals weighing less than five grams.

Histologic studies of the thymus glands of our thymus-injected strain of rats have been made in several generations, but have shown nothing startling beyond an enlarged succulent gland, overpopulated with lymphocytes, which have spread from the cortex into the medulla. At the same time there seems to be a paucity of Hassall's corpuscles, the whole gland resembling those encountered in extremely healthy, well-fed or overfed animals. Changes in the other organs of these animals have not been sufficiently striking to warrant comment, with the possible exception of the pituitary.

Numerous counts on a series of animals of the thymus-injected strain have been made by one of us (C) in the various age groups up to forty-five days, and these have been compared with counts made on a series of Institute control animals of similar ages. In all about eighty pituitaries have been counted, divided about equally between test and control animals. To date it appears that the adult pattern (cell distribution) of the thymus-injected animals is reached at an earlier period than in the control strain, although it should be admitted that our control animals do not conform to the normal counts reported by Wolff and Severinghouse, particularly in the acidophile count. The thymus-injected animals reach the

adult count of acidophiles of our control animals about ten days earlier than the controls.

While the effects of pineal injections have been, in some ways, even more interesting and striking than those following the administration of thymus extract, we have not been successful, as yet, in establishing a constant picture from either the ablation or implantation of the pineal gland. Success or failure in each instance may be dependent on quantitative factors since the extract employed represents in pineal tissue at least one hundred times the weight of the normal pineal gland of the rat. To date, therefore, our sole evidence in reference to the pineal gland concerns the effects, identical in nature, using either the picric acid containing extract or the aqueous HCl extract.

Conclusion

From these studies the conclusion seems inescapable that the functions of the thymus and probably also of the pineal gland concern the rate of growth and development of the young. The rate of growth is accelerated by the thymus and retarded by the pineal gland, while the rate of development is accelerated by both glands.

SLENDERIZING DRUG AND BLINDNESS

A news dispatch from California says that research workers of Stanford University Medical School are endeavoring to learn whether dinitrophenol, newly developed "anti-fat" drug, was responsible for the temporary blindness of twelve San Francisco Bay district women who have been stricken recently.

All of the women had taken the drug in an attempt to reduce, Dr. Loren Chandler, dean of the school, reported. Dr. Chandler and Dr. Walter W. Boardman, who reported

the cases to the *Journal of the American Medical Association*, said the blindness resulted from the formation of cataracts over the eyes, but it was not yet known whether the cataracts were caused by the drug or by malnutrition, unbalanced diet or other factors.

It was estimated 1,000,000 persons in the world, including about 100,000 American women, are using the new drug. Dr. Chandler warned that school authorities "advise against its use for the present."

District Branch Meetings

The Annual Meetings for 1936 have been arranged on the following schedule:

September 17, Thursday—Sixth District Branch—*Ithaca*.

September 22, Tuesday—Third District Branch—*Albany*.

September 24, Thursday—Seventh District Branch—*Willard*.

October 1, Thursday—Fifth District Branch—*Rome*.

October 2 and 3 Friday and Saturday—Fourth District Branch—*Plattsburgh*.

October 7, Wednesday—First District Branch—*Morrisania Hospital, New York City*.

October 15, Thursday—Eighth District Branch—*Buffalo*.

November 19, Thursday—Second District Branch—*Garden City*.

SURGERY IN ESSENTIAL HYPERTENSION

FREDERICK S WETHERELL, M D, *Syracuse*

Much excellent research has been done, both from the clinical and laboratory viewpoints, on the subject of essential hypertension. What follows is in the nature of comments on the application of surgical methods for relief of the condition and a necessarily curtailed discussion of the rationale.

Routine physical examination often discloses for the first time that an individual has a blood pressure above normal to a degree which makes the physician suspicious that he is dealing with a case of essential hypertension. Careful investigation may then bring out the facts that headaches of unusual severity have been noted, that at times palpitation and forceful beating of the heart occur on slight exertion or during emotional disturbance, and that usual activities cause an untoward degree of fatigue. These manifestations are paroxysmal in nature and the same is true of the rise in blood pressure during which the symptoms become manifest. The degree of severity of symptoms is as a rule in direct proportion to the relative rise in pressure.

Among the objective findings are

- 1 An abnormal rise in pressure following the "cold pressor" test devised by Keith and coworkers. With one hand in ice water the blood pressure is taken in the opposite arm. The rise in pressure in hypertensive disease is up to ten times as great as in the normal. This test is of outstanding value. It should be used as universally as the sphygmomanometer in questionable cases.

- 2 Spasm of the retinal vessels is also an early finding. It precedes retinal hemorrhages and the papilledema found in later stages or rapidly progressing cases.

- 3 An increase in the thickness of the small peripheral arteries can be demonstrated under the microscope.

Classification

The classification which divides essential hypertension into groups should be valuable to the surgeon as an aid in determining not alone the advisability of applying surgical measures for its relief,

but also in suggesting the type of operation to be applied.

Keith¹ and his coworkers have given us such a classification based on progression of the disease. Adson's² analysis of this grouping is such an excellent one that I take the liberty of quoting it verbatim. He says:

In grouping cases of hypertension according to the progress of the disease, Keith has called those with slow progression *benign* hypertension, those with moderate progression *early malignant* hypertension, and those with rapid progression *malignant* hypertension, since he hoped that these terms, benign, early malignant, and malignant, would indicate not only the rate of progress, but would also signify the character of the symptoms, for example, that "malignant" would not only signify that the disease was rapid in its progress, but that symptoms were also very marked. This classification is slightly misleading since the patients with benign hypertension in the latter stages will present as marked cardiovascular and renal symptoms as those suffering from malignant hypertension. However, in order to have a better understanding of the progressive nature of the disease, it is well to follow this classification until a better one has been developed. We, therefore, find that Keith's *benign* group, those in which the disease develops *slowly*, includes individuals in whom the disease originates between the ages of 40 and 55 years and continues for a period of 10 to 15 years before it develops to such an extent as to terminate life. In the earlier stages of benign hypertension, intermittent headaches and the presence of retinal arterial spasm are the only symptoms and findings present other than that of elevated blood pressure.

Keith's second group, *early malignant* hypertension, which develops moderately fast, begins during that interval between the eighteenth and fiftieth years of life and progresses for a period of 3 to 4 years before death results. Retinal arterial spasm is associated with hemorrhages and evidence of retinitis. The blood pressure is capable of rises of 200 millimeters of mercury systolic and 160 millimeters diastolic. Irreparable cardiac, coronary, and renal injuries

Read at the Annual Meeting of the Medical Society of the State of New York
New York City, April 29, 1936

present symptoms in later stages of the disease in this group

Keith's third group, *malignant hypertension*, which progresses *rapidly*, may occur during the same years as in the early malignant group. However, the life expectancy after the onset of symptoms in this group is much shorter and averages only 18 months. Examination of the fundus reveals arterial spasm, arterial sclerosis, retinitis, hemorrhage, and edema. The symptoms of cardiovascular and renal disease progress rapidly. The systolic blood pressure frequently rises to 250 to 300 millimeters of mercury and the diastolic to 160 millimeters of mercury.

This grouping, it seems to me, is of more significance to the surgeon than a mere aid to prognosis, as held by some. It may be a lead to the type of operation indicated in an individual case.

Types of Operation

At the present writing, four types of operation have been advocated as relief measures. They vary in technical difficulties as well as in the results obtained. Each of these methods has been described in detail²⁻⁶ and only sketches of the procedures are here presented.

Rhizotomy. Following laminectomy, the anterior spinal roots are sectioned in varying numbers, usually from the fifth thoracic to the upper lumbar region. Such ablation removes the sympathetic nerve supply to the splanchnic vessels and cuts the motor supply of the abdominal musculature. It is conceded to be a formidable task and would hardly be applicable in a "bad risk" case. That it causes vasodilatation of the splanchnic area and furnishes a vascular bed which can receive a large amount of blood during a paroxysm of high pressure is without question.

Sub-Diaphragmatic splanchnic nerve and celiac plexus resection plus partial resection of adrenals. Through a long kidney incision the sub-diaphragmatic area is approached. A portion of the twelfth rib is excised. The entire operation is extraperitoneal. The splanchnic nerve bundle is picked up at its point of emergence through the diaphragm and as much as possible is resected along with a lateral portion of the celiac plexus. Additional removal of the upper two lumbar ganglia adds to the area of splanchnic vessel dilatation. Following this, the perinephritic tissue is incised the superior pole of the kidney brought toward the surface and the suprarenal gland transfixed with a suture. One-half to three-fourths of the gland is

then removed. The operation is done in two stages. Carrying the lower end of the incision forward to the anterior superior spine aids in the exposure.

Supradiaphragmatic splanchnic nerve resection. A longitudinal incision is made over the vertebral ends of the last three or four ribs. A sub-periosteal resection of approximately two inches of the eleventh rib is made. The transverse process of the eleventh thoracic vertebra is removed. I have found it decidedly advantageous to remove the process flush with the body. Overhang adds to technical difficulties. The greater, lesser, and minor splanchnic nerves are resected. In addition, the four or five lower thoracic ganglia and rami may be removed. This adds little to the technical difficulties and may add to the beneficial results. The last statement, a personal observation, is made in view of the definite right abdominal wall relaxation which followed a resection of the fifth to the eleventh thoracic ganglia and rami on the right side as a relief measure for visceral pain.

Resection of adrenal tissue. This operation needs only to be mentioned. The technique is well-known and is the same as applied in the removal of adrenal tumors.

Comment

The disease varies greatly in its manifestations in individuals. In one patient it may be rapidly fatal, in another run an attenuated course. It may be extremely disabling in one case, yet with objective findings of like nature, another may carry on an almost normal existence. Such findings indicate that we are dealing with great variations in the sensitiveness of sympathetic nervous systems. This lability undoubtedly extends from the frontal area, through the hypothalamic centers, to the remotest endings in smooth muscle fibers.

Medical treatment had been the only recourse for alleviation of the disease up to the time that sympathetic nerve surgery suggested the possibility of creating conditions which would lessen the severity of the paroxysmal rises in blood pressure.

The former must of necessity spend the major part of its activity in control of the central factor. Drugs, except mild sedatives, have proven valueless. Surgery, at least today, can only attack the distal factors.

Basically, it is diminution in the size of the smaller arteries which determines a rise in blood pressure. In essential

hypertension, a spasm and eventually a thickening of the wall of the arterioles determines the rise. This result is due to vasoconstrictor activity of the sympathetic nerve fibers. Vasoconstriction is a normal function and only becomes abnormal in the presence of an unstable, hypersensitive, sympathetic nervous system, one which responds to emotional or other stimuli in a degree not possible in the normal. This can be proven by a comparison of blood pressure readings of normal individuals who have been subjected to excitements of the same nature as those received by patients with varying degrees of hypertensive disease. Emotion may increase the systolic pressure as much as sixty millimeters Hg and the diastolic twenty-five millimeters Hg, whereas the normal does not show a rise of more than twenty millimeters systolic and from five to eight millimeters diastolic under like conditions.

Into this picture must be fitted the activity of the adrenal glands. The sympathetico-adrenal mechanism is a most important factor in the coordinated physiological reactions which maintain most of the steady states in the body (homeostasis).⁷ That an increase in secretion has a more marked effect in hypersensitive sympathetic states than in the normal is well-known. The classical reaction to epinephrin injections in hyperthyroidism is an example. The fact that the sympathetico-adrenal mechanism has definite work to do in controlling the blood sugar, clotting time, and many other bodily activities must be considered when adrenal surgery is contemplated, if only to make use of this knowledge in pre- and post-operative investigations to determine variations in these functions, and to aid in estimating the value of partial adrenalectomy. That no apparent harm follows resection of portions of the adrenal glands is suggested by the reports of those who have attempted to control hypertension by such operations. That *prolonged* benefit results has not been proven.

General Discussion of Surgical Procedures

Splanchnic nerve ablation, either alone or with the addition of partial removal of adrenal medulla, is proposed as means

of furnishing the body with a large area free from vasoconstrictor activity (splanchnic area) and a diminution of adrenal secretion.

Because of the comparative simplicity of the supradiaphragmatic operation it is likely to gain favor over the other methods. This does not indicate that it will be the one to be preferred in all cases. Peet⁸ has reported a large number of cases operated in this manner and the results obtained indicate that it has a distinct value. It is the only large series reported and the fact that fifteen per cent of his cases have an apparent cure, thirty-seven per cent are symptom free, forty-eight per cent report some relief in symptoms although the blood pressure remains the same, merits consideration when surgery is contemplated.

My feeling is that this operation will be especially indicated in older patients in the benign, or early malignant group, who are unable to obtain relief by medical means, and in whom the more extensive operations might jeopardize life unduly. The following is an example.

Mrs I J, sixty-one year old woman whose livelihood depended on selling goods from house to house in a farm district, found that for five years she had increasing difficulty in carrying on her work. She had dizzy spells, a "heart consciousness," weakness, severe occipital headaches, insomnia, and depressed feelings. Her physician, Dr G R Lewis, after careful examination and prolonged medical treatment felt that the element of essential hypertension in the case might be relieved by surgical intervention. The patient's environment, and other conditions, precluded the chance for betterment by medical treatment. Her age made me hesitate about operating, yet after a consideration of all the elements involved it was decided to do a supradiaphragmatic resection plus removal of the 8th to 12th thoracic ganglia and ram. In a basal state her blood pressure readings were 1 35-190/94, 1 40-188/94, 1 45-184/90, 1 50-188/96, 1 55-182/88, 2 00-186/90. The cold test gave readings, after two minutes 2 07-236/114, 2 09-210/100, 2 11-200/96, 2 15-196/96, 2 30-190/94. Her emotional high point was 230/115. This was the usual reading in the office on arrival.

Eye findings indicated a very early retinal sclerosis, definite irregularities in caliber, discs normal. Family history one of hypertensive disease, both parents and one sister

having died of apoplexy between ages of sixty-two and sixty-four. One sister died at age of fourteen of "brain fever."

After a one stage bilateral operation the systolic pressure ranged between 160/90 and 190/100 while in the hospital. She was out of bed on the seventh day and left the hospital on the tenth postoperative day. Four months later the patient resumed her usual work. She was free of the very troublesome headache and she felt better in every way. Her blood pressure after a twenty mile trip to the city, and without rest was 180/90.

Of course, it is too early to draw conclusions from this case but it points to possibilities. The risk entailed in applying any of the other procedures would have been too great.

There is very little postoperative discomfort following the operation and the patients can as a rule be out of bed on the tenth day. Experience in thoracic surgery is of no little aid in the handling of the pleura in these cases. Puncture must be avoided. If it should occur, as happened to me on one occasion during the performance of a cervicodorsal sympathectomy, a well-soaked saline sponge prevents air suction until the wound can be closed tightly. This is the complication which has decided some surgeons against employing the supradiaphragmatic approach.

Certain excision of the three splanchnic nerves is assured by the infradiaphragmatic approach. The possibility which presents for removal of a portion of the celiac plexus adds the effect of partial adrenal denervation. In the light of Crile's observations⁸ the value of this effect is in doubt. Removal of a portion of the adrenal gland may be accomplished at the time and may be of distinct value as an adjunct to the splanchnic dilatation resulting from the first step in the operation. At least, in the light of present knowledge, it leaves nothing undone. It is more extensive than adrenalectomy alone, but it leaves the splanchnic vessels without a vasoconstrictor influence, which is desirable. A large vascular bed capable of being dilated during rises in blood pressure results. Theoretically, this should relieve the other vessels of the body from the stress which accompanies the great swings of pressure. It seems reasonable to suggest that the inferior approach should be utilized in cases in which the progress is more rapid and the

patient in condition to withstand the more extensive work entailed, in other words, the early malignant group. The mortality rate of the infra- and supradiaphragmatic operations should be about the same in a given case but it seems that a greater number of patients could withstand the latter procedure. In both instances the mortality rate is low enough to warrant applying them as relief measures.

Because of the uncertainty of what will happen to the remnant of adrenal tissue remaining after resection without splanchnic nerve removal, it seems reasonable that until more is known regarding this question, the operation of nerve ablation should always accompany removal of the adrenal tissue.

In the malignant group, rapidly progressing to death, the risk of the operative procedure employed may fairly be considered as of secondary importance to the possibility of gaining relief and prolongation of life. Further *clinical research* will determine which of the measures will be of greatest value. Rhizotomy, perhaps with addition, at a later time, of adrenal resection, may prove to be the method of choice.

Conclusions

The author realizes that some internists feel that this problem is purely a medical one and that in the treatment of essential hypertension surgery is not yet to be considered of value. As to the latter feeling, the increasing number of reports of encouraging results following operation indicates that surgery will be of great aid as an adjunctive measure. No claim has been made to specificity of either sympathetic nerve resection or adrenal surgery. No well-informed surgeon will make such claims.

Medical treatment properly carried out will undoubtedly be sufficient in a large number of cases, yet no less an advocate of this method than White⁹ points to the necessity for the most painstaking and meticulous attention to detail, and the importance of having a patient intelligent enough to follow directions. Like the individual with peptic ulcer who cannot follow a regime and must come to surgery, so too there are many patients with essential hypertension whose educational endowments, or inherited common sense, or unwillingness to curtail normal activi-

hypertension, a spasm and eventually a thickening of the wall of the arterioles determines the rise. This result is due to vasoconstrictor activity of the sympathetic nerve fibers. Vasoconstriction is a normal function and only becomes abnormal in the presence of an unstable, hypersensitive, sympathetic nervous system, one which responds to emotional or other stimuli in a degree not possible in the normal. This can be proven by a comparison of blood pressure readings of normal individuals who have been subjected to excitements of the same nature as those received by patients with varying degrees of hypertensive disease. Emotion may increase the systolic pressure as much as sixty millimeters Hg and the diastolic twenty-five millimeters Hg, whereas the normal does not show a rise of more than twenty millimeters systolic and from five to eight millimeters diastolic under like conditions.

Into this picture must be fitted the activity of the adrenal glands. The sympathetico-adrenal mechanism is a most important factor in the coordinated physiological reactions which maintain most of the steady states in the body (homeostasis).⁷ That an increase in secretion has a more marked effect in hypersensitive sympathetic states than in the normal is well-known. In a basal state her blood pressure readings were 1.35-190/94, 1.40-188/94, 1.45-184/90, 1.50-188/96, 1.55-182/88, 2.00-186/90. The cold test gave readings, after two minutes 2.07-236/114, 2.09-210/100, 2.11-200/96, 2.15-196/96, 2.30-190/94. Her emotional high point was 230/115. This was the usual reading in the office on arrival.

Eye findings indicated a very early retinal sclerosis, definite irregularities in caliber, discs normal. Family history one of hypertensive disease, both parents and one sister

pathetic nervous system is of course that essential hypertension is due to overactivity of sympathetic stimulation. The reason for the removal of the splanchnics and the sympathetics is based on the supposition that there is an increased constriction of the arterioles in the splanchnic area from effector impulses over these routes. Recent careful investigations raise a grave doubt as to the validity of this assumption. It has been shown that the peripheral vasomotor reactions in hypertensive individuals are in no way different in character nor intensity from those of individuals with normal vessels. If the hypertension were due to increased vascular resistance in the splanchnic area the blood flow must necessarily be increased through the other vessels of the body, their caliber remaining the same. This is in accord with Poiseuille's law that the blood flow in any cross section of the vascular bed per unit of time is directly proportional to the pressure and inversely proportional to the resistance. Prinzmetal and Wilson further demonstrated that the vasomotor reactions in the hypertensive were of the same order as in the normal individual. This shows that hypertension is due to vascular hypertonus throughout the systemic circulation. There is, therefore, no valid

reason for any of the operations on the sympathetic system. The hypertonus is due to some factor as yet unknown. It does not appear to be a circulating pressor substance, although there may be such a substance not detectable by our present methods.

Essential hypertension from the medical standpoint is not in itself a condition which calls for drastic action. Many instances have been recorded with a course of over twenty years. At the present time the physician cannot predict in any given case when kidney damage will become evident. He can make a surmise that he is dealing with malignant hypertension when the individual is young and the progress is rapid. Malignant hypertension is a rapidly fatal malady, the average being one to two years from its onset. In these cases the physician is helpless. It seems that a surgical attack on such a group is justifiable if it holds any promise whatsoever. It is my feeling that surgery should be confined to this group and not used indiscriminately in all cases of essential hypertension. We should keep careful records and publish *late* results. I do not think that we have found the answer to essential hypertension and I think that it lies in some other direction than that which we are now following.

NEW FORM OF BIRTH CERTIFICATE

A new form of birth certificate, which differs in several respects from the one formerly used, has been placed in the hands of all local registrars of vital statistics of the State, outside of New York City.

The most important change was necessitated by the enactment into law of the Holley bill which provides that "there shall be no specific statement on the birth certificate as to whether the child is born in wedlock or out of wedlock, or as to the marital name or status of the mother." In accordance with this requirement, the item relating to legitimacy has, therefore, been omitted from the birth certificate. The law is to take effect September 1, 1936 and on and after that date it will be illegal for any local registrar to accept a birth certificate of the old type or a certificate of the new type which might

contain a specific notation regarding legitimacy. Thus, if a physician should mark a birth certificate "O W" (Out of Wedlock), the local registrar would be obliged to return it and request that a new form be filed without any identifying inscription.

The Holley bill reflects the views of the Governor's Commission which, under the chairmanship of Mr. Homer Folks, prepared and submitted to the Legislature last spring a comprehensive and forward-looking report on the important problem of illegitimacy.

Among the minor changes in the form of birth certificate of special statistical importance is the elaboration of the items relating to the residence of the mother, which will make it possible to allocate accurately all births recorded in the upstate territory. *Health News*, August 31.

MEDICAL RADIO BROADCASTS

The Medical Information Bureau of the New York Academy of Medicine announces the following broadcasts from Station WABC and the Columbia Broadcasting System network.

Thursday, Sept. 17, 1:30 P.M.—Speaker, Dr.

Albert H. Aldridge, Attending Surgeon, Womens Hospital. Subject, "Intelligent Motherhood."

Thursday, Sept. 24, 1:30 P.M.—Speaker, Dr. William J. Hoffman, Director of Tumor Clinic, Queens General Hospital, New York City. Subject, "Cancer Facts and Fallacies."

ties, precludes attainment of medical control. There are those of us who would rather end in a "blaze of glory" than to linger on in semi-invalidism for the sake of staying alive. It is so often impossible too, to change environmental conditions which may be a major factor in defeating the physician's efforts at control.

These, then, are points which must be considered, and which may decide the issue between medicine and surgery in an individual case.

The internist is the one who, after a thorough study of his case, must decide what is to be done. The surgeon must be equipped to survey intelligently the find-

ings of the internist, and then to apply the operation which experience indicates will result in the greatest benefit.

Least operative procedures fall into disrepute, it is incumbent on the surgeon to make a selection of cases with a view to obtaining an increasingly higher percentage of beneficial results. To achieve that end, the capacity for an intelligent review of the findings in each case is self-evident. Only by this manner of approach, it seems, will progress be made and surgical methods be given their proper relative value in the treatment of essential hypertension.

Discussion

DR. JOHN J MORTON, JR, Rochester—Dr Wetherell has given a very able presentation of the surgical attack on the problem of essential hypertension. You will note from his review that many different operations have been devised for handling this condition.

The most difficult operation from a technical standpoint is the long laminectomy with division of the anterior roots from dorsal VI to lumbar II. This is a severe operation even in the hands of the master surgeons who have advocated it. It has another disadvantage in that it causes a motor paralysis of the lower thoracic and upper abdominal muscles.

The simplest of the procedures is the extrapleural resection of the splanchnic nerves. This involves removal of a section of the XIth rib on each side. It is an operation carried out in a deep hole with artificially lighted retractors. The dangers are in pneumothorax and in bleeding from the azygas veins. It is not possible to be sure of the upper two lumbar nerve connections in this operation.

The subdiaphragmatic operation for splanchnic resection involves a wide dissection with more damage to the anatomical structures in the approach. It is possible to combine partial resections of the adrenal glands and division of the upper two lumbar nerve connections.

The operations for denervation or partial resection of the adrenal glands can be done by either the lateral subperitoneal or pos-

terior routes, or transperitoneally.

Denervation of the kidneys has been proved to be valueless.

The immediate results of most of these operations are quite striking. The surgeon can point with pride to lowered systolic and diastolic pressures, headaches are relieved, and the patients feel much better than they have for some time. It is said also that the changes in the eye grounds show marked improvement. As a rule, as time goes on however, the blood pressures slowly regain their previous level.

A perusal of the reported cases leaves a peculiar impression on the student of this problem. Crile, DeCoursey, Leriche, and Meillere, have all claimed striking results from operations on the adrenal gland alone. Adson and Craig who began with laminectomy and anterior root division, changed over to subdiaphragmatic splanchnic resection with partial adrenalectomy. They offered as explanation for Heuer's good results in anterior root division, that his cases were more carefully selected. Peet is apparently quite satisfied with his extrapleural splanchnic operation. Crile, who previously reported good results in early cases by adrenal denervation, has now changed to splanchnic resection. In other words, it appears that there is no unanimous approval of any of the operations. Some of the surgeons also seem to be looking for something to add to their previous operations as if they were not quite content.

The premise for the attack on the sym-

the short radio waves became concentrated in the drops of sweat which accumulated on the skin surface, producing arcing and burning. With the collaboration of Mr. Charles F. Kettering and Mr. Edwin C. Sittler, of the Research Laboratories of the General Motors Corporation, a simple and efficient air-conditioned cabinet was devised.* We were convinced, however, that the high cost and complexity of the combined radiotherm and air-conditioned cabinet militated against its usefulness.

After two years of constant experimentation with various modifications of the apparatus, an accidental observation caused us greatly to alter the method of producing and maintaining artificial fever. While subjecting a child with congenital syphilis to artificial fever therapy by the combined radiotherm and air-conditioned cabinet method, the nurse-technician failed to turn on the switches controlling the output of the high frequency currents. The rectal temperature reached the desired level of 106°F (41.1°C) in the usual time (50 minutes). It was then discovered that the high frequency currents had not been utilized for fever induction. By adjusting the air temperature-humidity factors in the air-conditioned cabinet the temperature was maintained at this level for the usual five-hour period.

This fortunate occurrence led us to develop a much simpler, safer, less costly, and more easily controllable air-conditioned apparatus (Kettering hypertherm) for fever production and maintenance (Fig. 1). High frequency currents are no longer employed. Deep tissue temperature studies made with thermocouples revealed no essential difference in deep heating effect when fever was produced by either high frequency currents (diathermy or radiothermy) or by conditioned air alone.

In its present state the Kettering* hyper-

therm consists of an insulated cabinet in which the nude patient lies, with his head extending outside the cabinet. Sponge-rubber insulation is utilized in the neck region to permit the patient to shift his position. The patient lies on an air mattress, supported by a boxlike bed, which is rolled in and out at will. In the rear of the cabinet is a small insulated fire-proof compartment in which the air-conditioning apparatus is housed. The dry-bulb air temperature is controlled by a thermostat. The percentage of relative humidity is controlled by a humidistat. The air velocity within the cabinet is controlled by blowers of fixed speed. The average set of air conditions to which the patient's body is subjected during fever induction is as follows: dry-bulb air temperature of from 130 to 150°F (54 - 65°C), relative humidity of from thirty-five to fifty per cent, and air velocity of 425 cubic feet per minute. The elevation of the rectal temperature to 105°F (40.6°C) is ordinarily accomplished in from forty minutes to one hour. During fever maintenance the dry-bulb temperature and air velocity are reduced. The air is constantly conditioned by continuous passage through the air-conditioning compartment. The safety and comfort of the patient are greatly enhanced by the accurate control of the relative humidity.

The mechanism of fever induction with the Kettering hypertherm depends primarily on heat transfer by conduction from the circulating heated air. This factor, combined with prevention of the normal rate of heat loss from the body by radiation and evaporation, is responsible for the elevation of the body temperature and its maintenance at any desired level.

The simplification of the apparatus and the removal of hazards inherent in certain other physical modalities, have converted this form of therapy from one requiring hospitalization to one in which the patient is usually able to return to his work on the day following treatment.

Early in the course of this investigation we discovered that the sense of exhaustion commonly experienced by many of our patients could be largely overcome by supplying large quantities of chloride-containing fluids. Most patients lost between two and five liters of sweat during

* Fifty-five of these units have been lent to twenty medical research centers, strictly for investigative purposes. The physicians and nurses charged with this undertaking received special training in the Department of Fever Therapy Research at the Miami Valley Hospital before the apparatus was released. A simpler, smaller and less costly apparatus is now being developed. It is probable that this apparatus will ultimately be available on a loan-lease basis to certain qualified institutions.

ARTIFICIAL FEVER THERAPY OF SYPHILIS AND GONOCOCCIC INFECTIONS

WALTER M. SIMPSON, M.S., M.D., F.A.C.P., *Dayton, O.*

Director, Kettering Institute for Medical Research, Miami Valley Hospital

The monumental researches of the Viennese physician, Julius Wagner-Jauregg,¹ announced in 1918, provided the stimulus which has led to the present remarkable interest in artificial fever therapy. For centuries, most physicians regarded fever as an alarming symptom of disease. After Virchow had ascribed various degenerative tissue changes to the effect of fever, the use of antipyretic drugs became common practice. Since Wagner-Jauregg's demonstration that artificial fever, induced by malaria inoculation, was frequently capable of overcoming the ordinarily disastrous effects of syphilis of the central nervous system, it has become more and more apparent that fever is one of the most important mechanisms of defense against infection. There is a growing body of evidence which indicates that fever exerts an adverse influence upon the growth of certain bacteria, diminishes the potency of toxins, favors phagocytosis, and stimulates the development of immune bodies.²

Wagner-Jauregg's success in the malaria therapy of dementia paralytica was soon confirmed by investigators in many parts of the world. The inherent dangers of engrafting one serious disease upon another as a therapeutic measure naturally led to a diligent search for a less hazardous method for producing a similar effect. Comparable results were obtained by other workers following inoculations with the organisms of rat-bite fever and relapsing fever. Repeated injections of vaccines prepared from typhoid or paratyphoid organisms or from *hemophilus ducreyi*, heteroproteins such as milk or peptone, and chemical substances such as sulphur, have yielded comparable

results in those cases in which sustained high fever was induced. It became more and more apparent that simple fever production was the important, if not the only, factor in the production of similar therapeutic results with such a wide variety of fever producing agencies. It was natural that these observations should stimulate a search for physical methods for artificial fever production.

Schamberg and Rule (1926), and Mehrtens and Pouppirt (1929) reintroduced the prolonged hot bath for thermotherapy. Rosanoff (1928) reintroduced the outmoded hot air method. Neymann and Osborne (1929), King and Cocke (1930), and Whitney (1930) introduced the use of high frequency electric currents (diathermy and radiothermy).

Investigations in the artificial production of fever by physical methods were begun at the Miami Valley Hospital in 1931. Several months of experimentation with hot baths, hot air, electric blankets, and diathermy convinced us that these physical modalities possessed inherent hazards, even though comparable clinical results could be obtained with any of these methods.

Experiments were then begun with an ultrahigh frequency oscillator, known as the radiotherm, developed by Whitney and his associates³ in the Research Laboratories of the General Electric Company. The apparatus was essentially a 1-kilowatt radio transmitter in which the condenser discharges were concentrated between two large metal plates instead of being directed from an aerial. The apparatus produced a high frequency field of approximately ten million cycles per second (30 meter waves) between the condenser plates. Early in the course of this investigation it became apparent that the comfort of the patient would be greatly enhanced by utilizing some form of insulated air-conditioned cabinet. This measure was necessitated by the fact that

With the collaboration of Charles F. Kettering, Sc.D., Edwin C. Sittler, B.S. in Engineering, Fred K. Kislig, M.D. (deceased), H. Worley Kendall, M.D., L. G. Kauffman, M.D., Arthur M. Culler, M.D., and Jerome Hartman, M.D.

Forty-five patients were treated for gonococcal arthritis, twenty-eight patients received treatment for gonococcal infection other than gonococcal arthritis

I Treatment of Syphilis

Many observers⁶ have found fever therapy combined with or followed by chemotherapy to be more effective than fever therapy alone in the treatment of neurosyphilis. On this basis we have combined chemotherapy, usually in the form of bismuth arspenamine sulphate (Bismarsen), with the fever treatments. In some patients neoarsphenamine (30 injections, each containing 0.3 gm.) and bismuth (30 injections, each containing 0.2 gm. of metallic bismuth) therapy was substituted. One advantage of the induction of artificial fever by physical methods is that the antisyphilitic drug may be given during the course of fever treatments. It is our practice to inject the antisyphilitic drug half an hour before the fever treatment is begun, on the basis that the general vasodilatation which occurs during sustained high fever may permit greater diffusion of the chemical substances. Bratz⁷ believes that fever produced by malaria increases the permeability of the small vessels of the brain and permits protective substances to reach the diseased brain tissues. After the ten sessions of fever therapy plus chemotherapy, twenty injections of the antisyphilitic chemical agents are given, at weekly intervals.

We have regarded a minimum course of artificial fever therapy for patients with syphilis to consist of fifty hours of sustained fever between 105 and 106° F (40.6-41.1 C). This more or less arbitrary choice is based on the observation that the highest remission rate following malaria therapy occurred in patients who had experienced at least fifty hours of fever above 102° F (39 C). The treatments are usually given in ten weekly sessions, each of five or more hours' duration. Many patients experience the most marked improvement after five or six treatments, a few require more than ten.

All patients are subjected to a thorough diagnostic survey to determine eligibility for fever therapy. Special studies are made of cardiac, vascular, and renal functions including electrocardiographic stud-

ies, basal blood pressure determinations and blood chemical analyses. Blood and spinal fluid serologic reactions, spinal fluid cell count, protein and sugar content, and colloidal gold reactions are determined before treatment is begun at the end of the combined fever-chemotherapy regimen, and at intervals of six months thereafter. As an additional control measure duplicate blood and spinal fluid specimens from these patients were submitted to Kahn in the laboratories of the University of Michigan Hospital for repetition of the serologic examinations. The Kahn standard diagnostic, presumptive and quantitative procedures* were carried out in those laboratories without any knowledge of the clinical condition of the patients, and reported to us.⁸ Old age (above 60 years), cardiac or renal insufficiency, advanced cardiovascular syphilis, aortic aneurysm, and the demented form of advanced dementia paralytica are regarded as contraindications. Patients between forty-five and sixty years of age are treated with great caution. One or more mild treatments are usually given such individuals as a test of cardiac function. Occasionally, treatments are spaced two weeks apart.

Early Syphilis

For centuries, laymen have known that sustained heat exerts a favorable influence on the cutaneous lesions of syphilis. The popularity of balneotherapy in many parts of the world has persisted since the ancient Greek priest-physicians first converted their thermal springs into baths. While emphasis has been placed on the mineral content of the waters, it now appears that the virtue of balneotherapy lies in its ability to produce local or general fever. The advent of scientific methods for the controlled production of fever provides a rational explanation for some of the results attained with the purely empirical use of these older methods.

A mass of experimental data is rapidly accumulating which provides strong evidence of the unfavorable influence of high body temperature on *Spirochete pallida*.

* The Kahn quantitative procedure was found to provide a reliable and sensitive index of therapeutic response.

a five-hour treatment at 106° F (41.1 C). The blood chloride values exhibited an average decline of forty mg per cent at the end of the febrile period in approximately eighty per cent of the patients. In five instances the fall exceeded one hundred mg per cent. Some patients exhibited such evidences of hypochloremia as nausea, vomiting, abdominal cramps, muscular twitchings or tetany. Chemical analysis of the sweat revealed an average

to 1,000 c.c. of a solution containing ten per cent of dextrose and one per cent of sodium chloride is slowly injected intravenously, without interruption of the treatment.

Treatment

During the past five years we have subjected 431 patients to 3,204 artificial fever treatments (approximately 17,000 hours of sustained fever). With the exception

Fig 1 The Kettering Hyperthermia

sodium chloride content of 650 mg per cent. Thus, from twenty to twenty-six grams of sodium chloride were being withdrawn from the blood and tissues during each treatment. Repeated gastric analyses revealed that the free hydrochloric acid completely disappeared during the first thirty to ninety minutes. These findings suggested the advisability of supplying chlorides during and immediately after each treatment. It was immediately apparent that the ingestion of two to four liters of 0.6 per cent sodium chloride solution (iced) largely abolished the symptoms of hypochloremia.

If nausea and vomiting persist, or if the patient is unable to take the required amount of chlorides by mouth, from 500

of occasional mild skin burns which occurred particularly at the beginning of this undertaking, no person has been injured by the treatments. One hundred and ninety-three patients, who have been under observation for six months to four and one-half years, have been treated for syphilis or gonococcal infection. Those patients who did not cooperate during the course of treatments or during the post-treatment progress studies, and all patients who have been under observation for less than six months, are excluded from consideration. There were thirty-one patients who received treatment for primary and early secondary syphilis, eighty-nine for neurosyphilis, ocular syphilis or resistant seropositive syphilis.

the end of fever treatment and remoculation, did not effect the results. Hence the fever treatment was effective at any stage of experimental syphilis in rabbits. The same authors investigated the thermal death time gradient of *Spirochete pallida* in testicular extracts *in vitro*. Five hours of temperature at 102.2° F (39 C), three hours at 104° F (40 C), two hours at 105.8° F (41 C), and one hour at 106.7° F (41.5 C) were required to render infective material innocuous to other rabbits.

Levaditi and de Rothschild¹⁷ carried out somewhat similar experiments in which thermocouples were used to determine local temperature, with less constant results. In many of the rabbits rapid healing of the primary lesions, disappearance of spirochetes, sterilization of lymph glands, and negative serologic reactions occurred. Levaditi regards artificial fever as an effective factor in stimulating the defense mechanism. Kolmer and Rule¹⁸ demonstrated that the testicular lesions were prevented and the inguinal lymph glands became sterile if rabbits inoculated intratesticularly with *Spirochete pallida* four days previously were immersed in water at 113° F (45 C) for twenty minutes daily for fifteen days. If, however, the testicular lesions were kept out of the heated water, active syphilitic lesions developed. These authors¹⁹ also found that fever of from two to five degrees F (11–28 C) which lasted several hours and which was induced in the rabbit by intravenous injections of increasing amounts of typhoid-paratyphoid vaccine or Coley's fluid showed much less effect on the course of acute testicular syphilis than did fever induced by hot baths.

We have confirmed the observations of Carpenter, Boak, and Warren by a somewhat different experiment. Six male rabbits were inoculated intratesticularly with fresh testicular extract containing the Nichols strain of *Spirochete pallida*. Only rabbits with negative Kahn and Kolmer serologic reactions were selected. Chancres or syphilomas developed in both testes of all the animals within four to six weeks. Aspiration revealed the presence of spirochetes in all. The serologic reactions of all were strongly positive at the end of eight weeks. Hemicastration

of each rabbit was then done. The testicular emulsion derived from the extirpated testis of each of these six rabbits was then injected into the testes of each of a new series of six seronegative normal rabbits, all developed chancres and positive serologic reactions in the usual time. Immediately after hemicastration, the syphilitic rabbits were subjected individually to sustained rectal temperature of from 107.1 to 108.1° F (41.8–42.4 C), average 107.6° F (42 C), for six hours, thirty-meter waves of a high frequency oscillator being used. The remaining testis was then removed from each rabbit four days after the fever treatment. Injection of testicular suspensions from each heated rabbit was made into the testes of each of a new series of seronegative normal rabbits, none developed evidence of syphilis, the serologic reactions of all remained negative.

It is quite conceivable that the same uniformity in results might not obtain following the application of fever therapy to human subjects. Syphilis in rabbits apparently pursues a somewhat milder course, generalized lesions and central nervous system involvement are comparatively rare. Nevertheless, these experimental studies provide incontrovertible evidence of the spirochetocidal effect of sustained high body temperature. Many observers are convinced that fever therapy is capable of producing a distinctly favorable influence on the progress of early syphilis, particularly when fever therapy is combined with orthodox chemotherapy. Kyrle²⁰ gave 232 seropositive patients with early syphilis (under two years duration) a course of arsphenamine (from 4 to 6 gm), followed by malaria therapy (ten chills), followed in turn by another course of arsphenamine therapy. The results were incomparably better than by any other method employed. Of the 232 seropositive patients with early syphilis, the blood serologic reactions were favorably influenced in 230 (99.1 per cent) after a single combined arsphenamine-malaria-arsphenamine course. Fifty-four of these patients had exhibited positive spinal fluid reactions. All were reversed to negative and remained negative. When Matuschka and Rosner²¹ reported on the work of Kyrle after his untimely death, not one of these patients had relapsed,

Many observers have reported their inability to find spirochetes in the brain tissue of patients who have died following malaria therapy.

In 1919 Weichbrodt and Jahnel⁹ placed rabbits with scrotal chancres in a thermostatically controlled incubator with the air temperature at 105.8° F (41 C). The temperature elevation in the rabbits induced by this procedure ranged from 104 to 107.6° F (40–42 C). The rabbits were subjected to this treatment for thirty minutes once or twice daily for from three to five weeks. After the second day the spirochetes gradually lost their motility, declined in number, and disappeared. The chancres healed much more rapidly than in untreated rabbits.

Schamberg and Rule¹⁰ in 1926 demonstrated that eleven hot baths on consecutive days, producing an average rise in the rabbits' temperature of four degrees F (2.2 C), when begun four days after the intratesticular inoculation of *Spirochete pallida*, would prevent the development of syphilitic lesions. They found that spirochetes heated on a water bath to 106° F (41.1 C) for six hours lost their motility and began to disintegrate. Their next experiment¹¹ showed that well-developed chancres of the scrotum of the rabbit disappeared after fifteen daily hot baths, each of fifteen minutes' duration. The average elevation of the rabbits' temperature was from 5.2 to 5.8 degrees F (2.9–3.2 C). In eight days the spirochetes had disappeared. The testicles were entirely normal in seventeen days. To determine whether the infection was completely extinguished, the popliteal and inguinal lymph glands were removed on the seventy-sixth day and injected into the testes of another rabbit. Eighty-seven days after the inoculation there was no evidence of infection. These experiments demonstrated that syphilis in the rabbit can be prevented and that primary syphilis in the rabbit can be cured by hot baths. In this connection, Schamberg states

The interesting query arises whether extremely hot baths might be effective as a prophylactic measure after exposure.

Schamberg and Rule¹² then employed hot baths on eleven human beings with syphilis. The patients received from one to fourteen baths, with an elevation of

mouth temperature to 105–106° F (40.6–41.1 C) for from thirty to fifty minutes. The eruptive lesions underwent marked and rapid regression. The serologic reactions were favorably influenced in practically all instances. At the conclusion of these observations, all were given the usual antisyphilitic chemotherapy. Schamberg and Tseng¹³ applied similar experiments to a few human syphilitic subjects, with essentially similar results.

Bessemans,¹⁴ of Ghent, and his associates have made valuable studies which demonstrate the feeble thermoresistance of *Spirochete pallida*. With the ingenious use of small thermocouples inserted into the scrotal chancres of rabbits it was shown that primary syphilis was cured by either local or general balneothermotherapy or arothermotherapy when the tissue temperature of the chancre was sustained at 104° F (40 C) for two hours or at 107.6° F (42 C) for one hour. Raising the rabbits' intratesticular temperature to the same levels after inoculation prevented the development of the disease.

The important researches of Carpenter, Boak, and Warren¹⁵ again emphasize the thermolability of *Spirochete pallida* and "suggest the practicality of fever therapy in the treatment of acute as well as chronic syphilis in man." Utilizing heat produced by the short radio waves of an ultrahigh frequency oscillator, they were able to prevent the development of chancres in twenty-one of twenty-five rabbits when treatments were begun four, five, and seven days after inoculation. In one treated rabbit a chancre developed, while the testis of another became edematous and indurated, increasing the duration and number of heatings caused the rabbits to become normal, two rabbits died. Eighteen untreated control rabbits developed the typical lesions of experimental syphilis. These workers also found that multiple unsustained fevers of from 105.8 to 107.6° F (41–42 C) destroyed *Spirochete pallida* in rabbits with active syphilitic lesions, as determined by reinoculation experiments. It was also found that one febrile period of six hours at a temperature of 106.7–107.6° F (41.5–42 C) was sufficient to destroy *Spirochete pallida*. The time interval between inoculations and fever treatment, or between

serologic reactions, as measured by the Kahn quantitative procedure, has occurred in all. The spinal fluid Kahn reactions remained negative in twenty-six instances, and were reversed to negative in five. There has been no evidence of clinical or serologic relapse in the patients treated with combined fever and chemotherapy.

With due regard to the small number of patients and the short interval of observation, these findings provide suggestive evidence that fever therapy alone or chemotherapy alone as applied to these patients) is often inadequate. These observations also suggest that combined fever and chemotherapy is a distinctly advantageous form of treatment for early syphilis, particularly in those patients who do not respond promptly to orthodox chemotherapy. It must be appreciated that this is strictly a preliminary report of the response of early syphilis to combined fever and chemotherapy. Every effort will be exerted to follow the progress of these patients, and others who follow, throughout their lifetime.

Under existing circumstances, strong forces operate to keep the patient with early syphilis from receiving adequate treatment. It requires about eighteen months of continuous therapy in cases of early syphilis and an indefinitely longer period for the treatment of late syphilis.²⁶ The high cost and inconvenience to the patient often result in inadequate treatment. More than a million persons seek authorized medical treatment for syphilis in the United States each year. Eighty-four per cent of the patients treated for early syphilis in five of the large clinics devoted to syphilis, failed to remain under treatment until the disease was rendered non-infectious. Usilton²⁷ has indicated that nearly two million persons in the United States are either inadequately treated or failed to receive any treatment for syphilis each year. Usilton has stated that "Syphilis as a treatment problem ranks first among the contagious diseases of man."

Any method that would appreciably decrease the time and expense involved in providing adequate therapy is worthy of thoughtful consideration. A growing body of evidence appears to indicate that artificial fever therapy fortifies and intensifies the curative action of chemo-

therapeutic agents. The advent of simpler and safer methods for the induction and maintenance of artificial fever should stimulate vigorous investigation of this possibility.

Neurosyphilis

Dementia paralytica Twenty-seven patients with dementia paralytica have completed the course of fifty hours of fever therapy plus thirty injections of chemotherapy. Twenty-one (77 per cent) have experienced clinical remission, three additional patients have been restored to a working status, two patients were accorded fifty per cent clinical improvement, one demented patient obtained no improvement. Clinical relapse has not occurred in any case in which remission occurred. Eight of these patients were committed to a local hospital for the mentally diseased, and were brought to the Miami Valley Hospital for treatment. Sixteen of the twenty-seven patients had received presumably adequate chemotherapy, two had relapsed after receiving malaria therapy, nine had received no treatment.

The Kahn serologic reactions were reversed to negative in seven, became less positive (Kahn quantitative procedure) in seventeen, and remained positive in three. The spinal fluid Kahn reactions were reversed to negative in six, became less positive in fifteen, and remained positive in six. The level of the colloidal gold reaction was reduced in nineteen, elevated in five, changed to negative in two, and remained unchanged in one. The spinal fluid protein content was reduced to approximately normal levels in fifteen, was elevated slightly in five, remained normal in four, and was unchanged in three. The spinal fluid cell count was either reduced to or remained within normal limits in all.

As with fever therapy induced with malaria, there is no parallelism between the immediate clinical response and the serologic or colloidal gold reactions. In most instances the serologic reactions become less positive or negative during a period of several months following the combined chemopvretotherapy.

Neymann and Osborne²⁸ have added to their own favorable experiences the observations of other workers in the appli-

clinically or serologically, during five years of observation

In the introduction to the Matuschka-Rosner monograph,⁶⁴ Finger makes this statement

The results are significant. They show that in the early period of syphilis nothing influences the serum and spinal fluid reactions so favorably as combined malaria arspenamine therapy, that a single course is usually sufficient, and that the earlier the treatment is begun, the better are the results

Kemp and Stokes²⁰ found that fever therapy induced by bacterial proteins, combined with arspenamine therapy and followed by arspenamine and bismuth therapy, offered a more satisfactory outlook in the treatment of early syphilis than routine chemotherapy alone

Richet and Dublneau,²¹ after experimentation with animals and human subjects, conclude that early syphilis may be "cured" more rapidly and more certainly by combined fever and chemotherapy than with chemotherapy alone. The blood serologic reactions of thirty-five of thirty-seven patients with primary and secondary syphilis became negative during or at the end of one course of pyretochemotherapy.

Wagner-Jauregg,⁶⁵ O'Leary,²² Jacobs and Vohwinkel,²³ Bering,²⁴ and others have repeatedly emphasized that the best form of treatment of neurosyphilis lies in its prevention by combined fever and chemotherapy during its asymptomatic phase. The extensive cooperative clinical studies carried out by Stokes, Cole, Moore, O'Leary, Wile, Clark, Parran, and Usilton²⁵ reveal that abnormal spinal fluid conditions were present in thirty-three per cent of patients with early syphilis, and in 56.1 per cent of patients with late secondary syphilis. The same observers have also stated that "even thoroughgoing (chemical) treatment does not necessarily prevent the development of abnormalities of the spinal fluid,"^{25b} and that in latent syphilis "almost all of the serologic response to be expected occurs within the first four months of treatment, thereafter further (chemical) treatment has little effect."^{25c}

On the basis of the foregoing observations it seems logical to conclude that the best results are obtained when combined fever and chemotherapy are applied early in the disease. With the hope that the

disastrous late neurologic, cardiovascular, and visceral manifestations of the disease might be prevented, we have subjected thirty-one patients with primary and early secondary syphilis to the combined fever and chemotherapy regimen (50 hours of sustained rectal temperature between 105–106° F (40.6–41.1 C) and 30 injections of antisyphilitic chemotherapy). None had received any previous treatment for syphilis. As a control measure, six patients with primary or early secondary syphilis were treated with only fifty hours of fever therapy at 105–106° F (40.6–41.1 C). In two of these patients clinical relapse (cutaneous eruption) occurred following the fever treatments, chemotherapy was promptly instituted. Of the four patients who have had fever therapy alone, the Kahn serologic reactions became less positive in all, the spinal fluid Kahn reactions remained negative in all.

A second control group of nineteen patients with primary or early secondary syphilis received thirty weekly injections of chemotherapy, without fever therapy. Clinical evidence of relapse (cutaneous eruption) occurred in four patients, fever therapy was then given, with prompt remission of the skin lesions. Of the fifteen patients who received only chemotherapy, the Kahn serologic reactions were reversed to negative in ten, became less positive in four, and became more positive (Kahn quantitative reaction) in one. The spinal fluid Kahn reactions remained negative in thirteen and were reversed to negative in two.

Including the six patients who were transferred from the two previous control groups, thirty-one patients with primary or early secondary syphilis were treated with combined fever and chemotherapy. The cutaneous manifestations of the disease including the chancres responded with surprising promptness. No living, motile spirochetes were found in any of the primary lesions after the first fever treatment. The Kahn serologic reactions were reversed to negative in seventeen, became less positive in eleven, and remained negative in three. Of the eleven patients whose serologic reactions became less positive, ten have been under observation for only six to nine months. Progressive decline in the intensity of the

serologic reactions, as measured by the Kahn quantitative procedure, has occurred in all. The spinal fluid Kahn reactions remained negative in twenty-six instances and were reversed to negative in five. There has been no evidence of clinical or serologic relapse in the patients treated with combined fever and chemotherapy.

With due regard to the small number of patients and the short interval of observation, these findings provide suggestive evidence that fever therapy alone or chemotherapy alone as applied to these patients is often inadequate. These observations also suggest that combined fever and chemotherapy is a distinctly advantageous form of treatment for early syphilis, particularly in those patients who do not respond promptly to orthodox chemotherapy. It must be appreciated that this is strictly a preliminary report of the response of early syphilis to combined fever and chemotherapy. Every effort will be exerted to follow the progress of these patients, and others who follow, throughout their lifetime.

Under existing circumstances, strong forces operate to keep the patient with early syphilis from receiving adequate treatment. It requires about eighteen months of continuous therapy in cases of early syphilis and an indefinitely longer period for the treatment of late syphilis.²⁷ The high cost and inconvenience to the patient often result in inadequate treatment. More than a million persons seek authorized medical treatment for syphilis in the United States each year. Eighty-four per cent of the patients treated for early syphilis in five of the large clinics devoted to syphilis, failed to remain under treatment until the disease was rendered non-infectious. Usilton²⁷ has indicated that nearly two million persons in the United States are either inadequately treated or failed to receive any treatment for syphilis each year. Usilton has stated that "Syphilis as a treatment problem ranks first among the contagious diseases of man."

Any method that would appreciably decrease the time and expense involved in providing adequate therapy is worthy of thoughtful consideration. A growing body of evidence appears to indicate that artificial fever therapy fortifies and intensifies the curative action of chemo-

therapeutic agents. The advent of simpler and safer methods for the induction and maintenance of artificial fever should stimulate vigorous investigation of this possibility.

Neurosyphilis

Dementia paralytica Twenty-seven patients with dementia paralytica have completed the course of fifty hours of fever therapy plus thirty injections of chemotherapy. Twenty-one (77 per cent) have experienced clinical remission, three additional patients have been restored to a working status, two patients were accorded fifty per cent clinical improvement, one demented patient obtained no improvement. Clinical relapse has not occurred in any case in which remission occurred. Eight of these patients were committed to a local hospital for the mentally diseased, and were brought to the Miami Valley Hospital for treatment. Sixteen of the twenty-seven patients had received presumably adequate chemotherapy, two had relapsed after receiving malaria therapy, nine had received no treatment.

The Kahn serologic reactions were reversed to negative in seven, became less positive (Kahn quantitative procedure) in seventeen, and remained positive in three. The spinal fluid Kahn reactions were reversed to negative in six, became less positive in fifteen, and remained positive in six. The level of the colloidal gold reaction was reduced in nineteen, elevated in five, changed to negative in two, and remained unchanged in one. The spinal fluid protein content was reduced to approximately normal levels in fifteen, was elevated slightly in five, remained normal in four, and was unchanged in three. The spinal fluid cell count was either reduced to or remained within normal limits in all.

As with fever therapy induced with malaria, there is no parallelism between the immediate clinical response and the serologic or colloidal gold reactions. In most instances the serologic reactions become less positive or negative during a period of several months following the combined chemopyretotherapy.

Neymann and Osborne²⁸ have added to their own favorable experiences the observations of other workers in the appli-

cation of artificial fever therapy by physical means to patients with dementia paralytica. Of 544 patients with dementia paralytica in all stages of the disease, 161 (30 per cent) obtained complete clinical remission, while 155 (29 per cent) were distinctly improved. Of forty patients with dementia paralytica treated by electropyrrexia, Neymann and Osborne obtained complete remission in twenty-five (62 per cent), and four additional patients were improved.

Hinsie and Blalock¹ have subjected 105 patients with dementia paralytica of the adult type to pyretotherapy, utilizing the short radio waves produced by an ultrahigh frequency oscillator. For purposes of comparison the patients were divided into three groups.

The first group, of fifty-one patients, was treated by artificial fever therapy only.

The second group, twenty-seven patients, was treated with an equivalent amount of thermotherapy and received six months later either tryparsamide and mercury therapy or a course of inoculated malaria.

The third group, of twenty-seven patients, received a similar course of pyretotherapy, followed immediately by one or more courses of tryparsamide and mercuric salicylate in oil.

The results achieved in the first two groups revealed that the addition of chemotherapy or malaria therapy after an interval of six months was of little or no benefit. In the group of patients treated by thermotherapy followed directly by chemotherapy, the clinical results were distinctly better. The remission rate of the patients of the first two groups one year after treatment was 21.7 per cent, while the remission rate one year after the termination of treatment in the third group of patients, who received pyretotherapy followed immediately by chemotherapy, was thirty-seven per cent.

Tabes dorsalis. Fourteen patients with tabes dorsalis received the course of fever-chemotherapy. All had received presumably adequate chemotherapy, three had received malaria therapy followed by a temporary remission. Ataxia (in all patients) and lancinating pains or gastric crises (in thirteen patients) were the chief complaints. Two patients with ataxia of three months' duration in one case, and of two years' duration in the other, were restored to normal gait, five

patients obtained seventy-five per cent improvement in gait, two obtained fifty per cent improvement in gait, and two obtained no improvement in gait. There appeared to be a direct relationship between the degree of improvement and the duration of the gait disturbance.

The root pains were abolished in all. Often the pains disappeared after the first two or three treatments. Recurrence of root pains occurred in three patients after the usual course of treatment; these patients required additional treatments to control the pains. Normal function was restored in two cases of urinary and fecal incontinence.

The Kahn serologic reactions were reversed to negative in four patients, became less positive in three, remained negative in one, and remained positive in six. The spinal fluid Kahn reactions were reversed to negative in three, became less positive in four, remained positive in three, and remained negative in four.

Tabetic form of dementia paralytica. Eight patients with the tabetic form of dementia paralytica were subjected to the combined treatment. All had previously received chemotherapy without influence upon the course of the disease, two had also received malaria therapy, followed by remission, lasting six months in one instance and one year in the other. Improvement in mental orientation occurred in six, two demented patients died, one seven months after the treatment was completed, the other fifteen months following the treatment. Subsidence of root pains occurred in all, in two instances additional fever treatments were required. Improvement in gait occurred in four of five patients with ataxia, one patient who had had a tabetic gait for three months was restored to normal gait. One patient with a "cord bladder" regained normal control of bladder function.

The Kahn serologic reactions were reversed to negative in two instances, became less positive in two, remained negative in three, and remained positive in one. The spinal fluid reactions were reversed to negative in four, became less positive in three, and remained positive in one.

Diffuse central nervous system syphilis. In this group are placed twenty-three patients with various manifestations of

symptomatic neurosyphilis, which could not be definitely classified as dementia paralytica, tabes dorsalis or the tabetic form of dementia paralytica. Nineteen of these patients had received presumably adequate chemotherapy, four patients had received no chemical therapy. There were eight cases of congenital syphilis and fifteen cases of acquired syphilis. Included in this series are sixteen cases in which symptoms and signs of exudative ocular syphilis predominated. Two patients had experienced hemiplegia following cerebral thrombosis, fever therapy exerted very little influence upon the residual effects of the hemiplegia. Among the twenty-three patients of this group, sixteen patients obtained symptomatic relief, five were moderately improved, two obtained no improvement. The Kahn serologic reactions were reversed to negative in four, became less positive in fourteen, remained positive in three, and remained negative in two. The spinal fluid Kahn reactions were reversed to negative in six, became less positive in three, remained positive in three, and remained negative in eleven.

Asymptomatic neurosyphilis. Of seven patients with asymptomatic neurosyphilis, all of whom had received apparently ineffectual chemotherapy, the spinal fluid Kahn reactions were reversed to negative in all. The Kahn serologic reactions were reversed to negative in four, remained negative in two, and became less positive in one. None has shown evidence of serologic relapse.

Ocular syphilis

Ocular complications²⁰ existed in fifty-eight of the syphilitic patients, including four patients with double classification (conjugate palsy and optic atrophy, uveitis and optic atrophy, uveitis and neuroretinitis, and neuroretinitis and choroiditis). The ocular complications may be classified as follows:

1 Extraocular palsies	4
2 Interstitial keratitis	11
3 Exudative uveitis	10
4 Optic neuritis and neuroretinitis	14
5 Choroiditis	7
6 Optic atrophy	16
	62

In the evaluation of the response of four patients with extraocular palsies to artificial fever therapy there was no evidence

that this method is superior to older forms of treatment.

Among the eleven patients with interstitial keratitis were eight who had experienced recurrences and ten who had failed to respond to chemotherapy. The duration of the disease and the tendency towards recurrence appear to be distinctly lessened following adequate fever therapy combined with chemotherapy. The response is most prompt in those cases in which an opaque central disc of plastic exudate exists. It is usually this type of the disease which produces the greatest visual damage.

In ten cases of exudative uveitis prompt clinical improvement became apparent in every instance after the first one or two fever treatments. With the exception of one patient who had advanced old degenerative changes, all have recovered useful vision. One patient experienced a mild recurrence, probably because of inadequate fever therapy. With due regard to the small number of cases in this series, the results were so uniformly favorable that we regard combined fever-chemotherapy as the treatment of choice in syphilitic exudative uveitis.

Favorable response occurred in the lesions of fourteen patients with optic neuritis and neuroretinitis. All recovered useful vision although nine have some residual pallor of the disc and some degree of field contraction. Active neuritis along the optic tract appears to be arrested by fever therapy.

Active choroiditis in seven patients subsided with fever therapy with residual scars and field defects. Good central vision has resulted in all but one eye.

In sixteen patients with optic atrophy the visual acuity and visual fields remained practically unaltered after a course of combined fever-chemotherapy. If optic atrophy is associated with foci of active infiltration along the optic tract it is quite probable that such exudative lesions will respond to fever therapy. Optic atrophy is not a contraindication to fever therapy.

From these observations it seems quite apparent that artificial fever therapy is most effective in the exudative lesions of ocular syphilis, and that the best results are obtained when pyretchemotherapy is instituted promptly after the first appearance of the exudative lesions.

Resistant seropositive syphilis

Included in this study were ten patients with so-called "Wassermann-fast" syphilis, or what we prefer to term resistant seropositive syphilis. All had had presumably adequate chemotherapy for at least two years. The Kahn serologic reactions were reversed to negative in five, became less positive in four, and remained positive in one. The spinal fluid Kahn reactions remained negative in all. Serologic relapse has not occurred in any of these patients.

II Treatment of gonococcic infections

It has long been known that *Neisseria gonorrhoeae* is a particularly thermolabile organism. There are many records of spontaneous recovery or remissions from the manifestations of gonococcic infections during intercurrent febrile disease. It is also well known that the gonococcus soon disappears and is replaced by secondary invaders when it reaches deep tissues, such as the Fallopian tubes. Neisser and Scholtz³⁰ found it difficult to cultivate the gonococcus in patients with fever. Bacteriologists have recognized that the organism does not grow well on artificial mediums at temperatures of 100.4°F (38°C) or above.

The recognition that fever exerts a favorable influence upon gonorrhea and its complications has led to treatment with fever produced by malaria inoculation or with chemical or foreign protein substances. While some satisfactory clinical results have been obtained by such methods, they have the drawback of being inconstant in their fever-producing properties and frequently provoke serious, uncontrollable, and occasionally fatal reactions. Localized fever treatments have been carried out, for the most part with high frequency electric currents such as diathermy or radiothermy. The chief objection to this procedure is that the heat treatment is limited to a localized area. Patients with gonococcic arthritis are suffering from a systemic disease, requiring systemic treatment.

The indefinite, and often contradictory, reports of the thermal death time of *Neisseria gonorrhoeae* have been clarified by the extensive thermal death time gradient studies made recently by Car-

penter, Boak, Mucci, and Warren.³¹ When it became apparent that gonococcic infections responded to artificial fever therapy if the fever was sustained for long periods at a high level, these workers set out to determine the thermal death time gradient of the gonococcus when subjected to temperatures that can be tolerated by man. The *in vitro* thermal death time of fifteen strains of *Neisseria gonorrhoeae* was determined at different temperature levels. Some of the strains had been under artificial cultivation for many years, while others had been isolated one to four months previously. At 102.2°F (39°C) growth was not appreciably affected. At 104°F (40°C), about 99.7 per cent of the organisms were killed by ten hours' exposure. At 105.8°F (41°C), ninety-nine per cent of the gonococci were destroyed in from four to five hours' exposure, the remaining one per cent required eleven to twenty-three hours. At 106.7°F (41.5°C) and 107.6°F (42°C), ninety-nine per cent of the gonococci were rendered non-viable in two hours, while the remaining one per cent required five to twenty hours. The cultures which had been under cultivation for only a short period were most susceptible to heat. From these studies it became apparent that it would be possible in most instances, to exceed the thermal death time of the organism without injury to the human host, by adapting the temperature level in patients with gonococcic infections to the thermal death time of the organism. We have repeated the experiments of Carpenter, Boak, Mucci, and Warren with essentially identical results.

There is, therefore, convincing evidence, based upon *in vitro* thermal death time studies and the clinical response of patients with gonococcic infections to artificial fever therapy, that it is possible, in most instances, to destroy gonococci in the various lesions of the disease with high sustained body temperature. In addition to this sterilizing effect, there is also evidence which indicates that artificial fever therapy stimulates immune reactions. In four of our patients with gonococcic urethritis, gonococci were present after four fever treatments. The organisms disappeared in from two to four weeks in these patients, providing

evidence that the stimulus to immune reactions produced by fever was responsible for the ultimate disappearance of the gonococci. Carpenter, Boak, and Warren³² have suggested that the duration of the fever treatment should be based upon the thermal death time of the strain of gonococcus responsible for the disease in each individual patient. They subjected eleven patients to a single fever treatment at 106.7° F (41.5 C), equal in length to the thermal death time (5 to 17 hours) of the cultures obtained from individual patients, following which there was a prompt disappearance of the gonococci and all clinical evidence of the disease. Similar results were obtained in nine patients when the fever period was one-fourth to three-fourths of the thermal death time, suggesting the assistance of the defense factors in the body in the disappearance of the disease.

In practice, we have found important objections to such a plan. It sometimes requires several days to carry out accurate thermal death time determinations. Occasionally the organism is recovered with difficulty. Individual patients may harbor multiple strains, which differ in their heat resistance. In rare instances, highly resistant strains require twenty or more hours at temperatures of 107° F (41.7 C) or above before they are destroyed.

For practical purposes we have found that four or five treatments, each of five to seven hours' duration, at a rectal temperature range of 106° F (41.1 C) to 107° F (41.7 C), at intervals of three to five days, are productive of prompt and satisfactory results in the great majority of cases. Early in the course of this undertaking, it was our practice to give the treatments at intervals of one week or longer. The more promptly favorable results obtained by Desjardins, Hench, Stuhler, and Popp,^{33, 35} convinced us of the necessity for altering our technic by giving the treatments at shorter intervals. The average interval between treatments during the first part of our work was 6.14 days. During the past two years the average interval between treatments has been 4.07 days. The average number of treatments was 4.9. Four treatments at intervals of three to five days, the interval depending upon the general condition of the patient and his tolerance of the

treatments, are usually regarded as a minimum course. If all evidence of activity, in either the joints or the genito-urinary tract, has not disappeared, additional treatments are given at equivalent intervals.

Gonococcic arthritis

One of the most frequent and disabling complications of gonorrhea is gonococcic arthritis. In a high proportion of cases permanent deformity and disability, affecting one or several joints, is the end result. The fact that so many different methods of treatment have been employed provides evidence of the inadequacy of most or all of them.

During the past three years, the outlook for patients with gonococcic arthritis has been enormously improved.

In March 1932, a thirty-nine year old man was referred to us for artificial fever therapy because of resistant seropositive syphilis. The history and physical examination revealed that the patient also had active chronic gonococcic arthritis of five months' duration, involving the right wrist. Gram-negative intracellular diplococci were found in large numbers in urethral smears. After the third artificial fever treatment, each of which consisted of five hours of fever above 105° F (40.6 C) at intervals of one week, all evidence of active gonococcic arthritis had disappeared. The joint function, which had been practically nil, was restored to ninety per cent of normal. The urethral smears became negative for gonococci after the fourth treatment and have remained negative since that time. Encouraged by this coincidental observation we decided to treat other cases of gonococcic arthritis.

Scattered reports^{36, 45} of favorable experiences in the treatment of gonococcic arthritis with artificial fever therapy have appeared in medical literature since 1932. The results obtained with a variety of physical modalities have been summarized and tabulated in a recent communication by Hench, Slocumb, and Popp.³⁴ Of thirty-three cases mentioned in the nine reports reviewed by these authors, data on the results obtained in the treatment of twenty-four patients could be calculated. Of these twenty-four patients, twenty-two (92 per cent) were "completely relieved" or "cured." Failure resulted in only two cases (8 per cent) and was attributed to inadequate fever production. Hench,

Slocumb, and Popp have treated sixteen patients suffering from gonococcic arthritis with artificial fever therapy, utilizing the Kettering hypertherm. Nine of the patients had acute arthritis, while seven had the disease in a chronic form. Eighty-eight per cent of the patients with acute gonococcic arthritis were promptly "cured," or practically so, while the remaining twelve per cent obtained marked improvement. Of the seven patients with chronic gonococcic arthritis, all but one were markedly improved. The authors state

In gonococcic arthritis, results are so striking and apparently so superior to those obtained by other methods, that we can prescribe fever therapy as the method of choice with considerable assurance.

Schnabel and Fetter⁴⁶ have reported their experiences in the treatment of eighteen patients with gonococcic arthritis, also utilizing the Kettering hypertherm. Of the nine patients with the acute form of the disease, six were cured, two obtained marked improvement, and one inadequately treated patient received moderate improvement. Five of the nine patients with chronic gonococcic arthritis (of more than six weeks' duration) were cured, three were markedly improved while one received only moderate improvement.

Anderson, Arnold, and Trautman⁴⁷ and Faget⁴⁸ of the U. S. Public Health Service (Marine) Hospitals at New Orleans and Norfolk, treated twenty-four patients with gonococcic arthritis, all but two were cured with one to seven treatments, the remaining two patients received distinct benefit.

We have completed the course of treatment of forty-five patients with gonococcic arthritis. Thirty-one were suffering with the acute form of the disease (less than eight weeks' duration), while fourteen had chronic gonococcic arthritis. Patients were not selected. The only requirements were that a diagnosis of gonococcic arthritis could be established and that the physical condition of the patient would permit him to tolerate the treatments. Contrary to common belief, multiple joints were usually affected. In thirty-two of the patients (71 per cent), the disease was polyarticular. Thirty-two of the forty-five had received some form of local chemical treatment of the genitourinary tract be-

fore the onset of arthritis. In the male patients this usually consisted of the installation of a silver preparation into the urethra. At the time of the diagnostic survey, prior to the institution of fever therapy, the urethra or cervical smears of thirty-two patients revealed the presence of gram-negative intracellular diplococci. Of the thirteen patients with negative smears, all had had positive smears just prior to the time of their admission to the Miami Valley Hospital. In no case was the infection restricted to the anterior urethra in the male. Of the ten female patients there were two with pelvic cellulitis, one with urethritis and Bartholinian abscess, and seven with acute cervicitis. Of the seven with acute cervicitis, two had urethritis, one had urethritis and bilateral salpingitis, one had bilateral salpingitis, and one had bilateral salpingitis and left tubo-ovarian abscess. Following the course of fever therapy for the treatment of gonococcic arthritis, all evidence of gonococcic infection of the genitourinary tract had disappeared in thirty-eight patients (84 per cent). Of the seven patients with persistence of genitourinary gonococcic infection, all evidence of the disease disappeared in four patients within two to four weeks without additional fever or local treatments. Two of the remaining patients with persistent genitourinary infection had received inadequate fever therapy (less than three treatments), the third had received apparently adequate fever therapy (five treatments), but the urethral smears remained positive. Supplemental local treatment eliminated all evidence of gonococcic infection of these three refractory patients.

Of the thirty-one patients with acute gonococcic arthritis, the average improvement in joint function immediately following the conclusion of the course of fever treatments was eighty per cent, in ten patients the restoration of joint function was complete. At the time of writing, the average improvement in joint function in the thirty-one acute cases is 99.7 per cent, twenty-nine of the patients with acute gonococcic arthritis now have complete restoration of joint function. Of the fourteen patients with chronic gonococcic arthritis the average improvement immediately following the course of fever therapy was 66.1 per cent. Of the fourteen

patients with chronic gonococcic arthritis, the average improvement at the time of writing is 92.8 per cent, seven patients have obtained complete restoration of joint function.

Worthy of particular mention are our experiences with two cases of chronic gonococcic arthritis, in which almost complete limitation of motion of one knee joint remained after the usual course of fever therapy. After all evidence of active inflammation had disappeared, the joints were manipulated under general anesthesia (brisement force) in order to separate the fibrous adhesions. Fever therapy was immediately instituted following the surgical manipulation. In both cases practically complete joint function has been restored. Orthopedic management is a requirement in those cases of chronic gonococcic arthritis in which partial ankylosis has occurred prior to the institution of fever therapy.

Gonococcic infections, other than arthritis

The distinctly favorable experiences of Desjardins, Stuhler, and Popp,^{33, 35} Bierman and Horowitz,⁴⁰ Carpenter, Boak, and Warren,³² Anderson, Arnold, Trautman, and Faget^{47, 48} have provoked a lively interest in the fever therapy of gonococcic urethritis, cervicitis, vaginitis, salpingitis, prostatitis, seminal vesiculitis, epididymitis, ophthalmia, and dermatitis blennorrhagicum. Desjardins et al., subjected seventy-six patients with simple or complicated gonococcic infection to fever therapy in the Kettering hypertherm, of these, sixty-eight (89.5 per cent) were cured, and the condition of seven (9.2 per cent) was improved, in only one patient did the infection prove refractory to fever treatment. The average number of treatments was six. In a report of the progress of these patients, Stuhler⁵⁰ stated:

I believe that the introduction of fever therapy for gonococcic infections is one of the greatest advances made in the last fifty years. I believe it is of even greater importance to the clinician than was the discovery of the gonococcus by Neisser in 1879.

Bierman and Horowitz⁴⁰ have achieved excellent results by an ingenious combination of systemic hyperpyrexia (105-

107° F, 40.6-41.7 C) with simultaneous additional heating of pelvic structures (to 111-112° F, 43.8-44.4 C) by diathermy electrodes especially adapted to the vagina or rectum.

We have treated twenty-eight patients with gonococcic infection, other than gonococcic arthritis. There were twenty-three men and five women, whose ages ranged from eighteen to fifty-eight years. Eighteen were suffering with the acute form and ten with the chronic form of the disease. Eighteen patients (64 per cent) had received some form of local chemical treatment of the genitourinary tract prior to the institution of artificial fever therapy. Eight patients with acute gonococcic urethritis had received orthodox local treatment for an average of five weeks prior to fever therapy, the ten patients with chronic gonococcic urethritis had received local treatment for from two months to five years.

The average interval between the onset of gonorrhea and the institution of fever therapy was twenty-four days in the acute cases, in seven of the chronic cases the average interval was seven and one-half months, while the interval was from four to seven years in the remaining three cases.

Only one of the male patients had simple acute anterior urethritis, in all of the others there was extension to the posterior urethra, prostate, seminal vesicles or epididymis. In none of the five female patients was the infection localized to the urethra or cervix. All had pelvic cellulitis, while one had associated Bartholinian and bilateral tubo-ovarian abscesses.

The average number of treatments given to the twenty-eight patients was 3.32, approximately the same number of treatments were given to patients with either the acute or chronic form of the disease.

The average interval in the treatment of the first nineteen patients was 6.58 days. After we had learned that favorable results were more prompt and uniform when the interval between treatments was shortened, we altered our program. The last nine patients to be treated received an average of 3.5 treatments at an average interval of three days.

At the conclusion of the course of

fever therapy all evidence of gonococcal urethritis and its complications had disappeared in twenty-five (89 per cent) of the twenty-eight patients. No other form of treatment was employed in these patients. In one patient gonococcal ophthalmia responded to the first treatment. In two patients with dermatitis blennorrhagicum, the skin lesions disappeared after one treatment in one case and after two treatments in the other. Two male patients and one female patient, treated at irregular and long intervals (7 to 14 days), had persistently positive smears or cultures. All received apparently inadequate fever therapy (two treatments in two cases and three treatments in the third). In the female patient, who had acute gonococcal cervicitis and bilateral salpingitis, the pelvic complication disappeared after fever therapy, but positive cervical smears remained. After additional local treatment, the smears of all three became negative within two weeks.

Comment

With two exceptions, all of the persons with syphilis were treated as ambulatory patients. During the past year we have found that it is distinctly advantageous to admit patients with gonococcal infections to the hospital for a period of two weeks. We have found this to be particularly desirable in cases of gonococcal arthritis. This plan permits close supervision of the patient and eliminates the uncooperative patient.

Artificial fever therapy by physical means is not a simple undertaking. In the hands of unskilled or unscrupulous persons it is fraught with danger. History is repeating itself in the attempts of certain manufacturers to exploit the field by utilizing modern high-pressure sales methods. Some of the apparatus now available through commercial sources is inadequate and dangerous and is sold to any physician without thought of adequate training of the supervising physicians and his technical assistants. Three important considerations are involved in the proper application of artificial fever therapy. The *first* is the thorough training of the supervising physician in the physical and the physiologic aspects of the undertaking. The *second* is the adequate training of the nurse-technicians. The *third*, and perhaps

the least important consideration, is the apparatus. The undertaking is in many respects comparable to a major surgical operation, particularly as regards the necessity for a careful diagnostic survey to determine eligibility and the constant attention to the patient by physician and nurse-technician during the long treatment. It is well to re-emphasize the obvious, but too often disregarded fact, that skill of personnel far transcends in value the perfection of matériel. The nurse-technician should receive at least one to two months of special training before undertaking this work. Exceptional alertness and intelligence are primary qualifications.

It seems quite apparent that artificial fever therapy by physical means should be restricted to institutions in which the physician and nurse personnel has received adequate preliminary training. The production of effectual artificial fever is not adaptable to ordinary office practice. Unless these precautions are exercised this important adventure in therapeutics is almost certainly doomed to a period of discredit not unlike that which followed the introduction of Roentgen rays. In the hands of skilled and devoted workers this form of therapy seems destined to occupy an increasingly important place in therapeutics.

Summary and Conclusions

- 1 The value of artificially induced fever therapy as an adjunct to chemotherapy in the management of neurosyphilis is now firmly established. The one factor common to the wide variety of infections, chemical, and physical methods that have yielded comparable therapeutic results appears to be simple fever production.

- 2 A simplified, controlled, and relatively inexpensive method for fever induction and maintenance (Kettering hyperthermia) has been devised. High frequency electric currents are not employed. During the past four years, 431 patients have been subjected to 3,204 artificial fever treatments, without any serious ill effects related to the method of treatment.

- 3 The frequent observation that the best results occurred when neurosyphilis was treated by combined fever and chemotherapy during its earliest mani-

festations led us to apply the treatment to patients with primary or early secondary syphilis. The results provide evidence that fever therapy may be of great value in early syphilis, particularly when chemotherapy alone appears to be inadequate.

4 The results obtained in the treatment of symptomatic neurosyphilis, asymptomatic neurosyphilis, ocular syphilis, and resistant seropositive syphilis are at least comparable, if not superior, to the results obtained with the more hazardous, time consuming, and inconstant malaria therapy.

5 Hospitalization is not a requirement for fever therapy by physical means.

6 The advent of simpler and safer methods for the production of artificial fever should stimulate vigorous investigation of the possibility that the time, effort, and expense involved in the adequate therapy of syphilis may be greatly lessened.

7 There is evidence that artificial fever therapy fortifies and intensifies the action of antisyphilitic chemotherapeutic agents.

8 High, sustained, controlled artificial fever is the treatment of choice for gonococcal arthritis. Gonococcal arthritis is a manifestation of a systemic disease, requiring systemic treatment.

9 *In vitro* thermal death time studies, and the clinical response of patients with gonococcal infections to artificial fever therapy, indicate that it is possible, in most instances, to destroy gonococci in the various lesions of the disease with high, sustained body temperature. In addition to this sterilizing effect, there is evidence that artificial fever therapy stimulates immune reactions.

10 Forty-five patients with gonococcal arthritis, associated with gonococcal infection of the genitourinary tract, have been treated with artificial fever therapy. Of thirty-one patients with acute gonococcal arthritis, the average improvement in joint function immediately after the conclusion of the course of fever therapy was

eighty per cent, in ten patients the restoration of joint function was complete. The ultimate average improvement in joint function in the cases of acute gonococcal arthritis was 99.7 per cent, twenty-nine have obtained complete restoration of joint function. Of the fourteen patients with chronic gonococcal arthritis the average improvement in joint function at the conclusion of the course of fever therapy was 66.1 per cent, the ultimate improvement in joint function in these cases was 92.8 per cent, in seven patients all evidence of joint disease disappeared. After the course of fever therapy, all evidence of genitourinary tract infection had disappeared in thirty-eight patients. The smears and cultures of four additional patients became negative within two to four weeks without additional treatment of any kind. Supplemental local treatment eliminated all evidence of gonococcal infection in the remaining three refractory patients, two of whom had received inadequate fever therapy.

11 In two cases of chronic gonococcal arthritis almost complete limitation of motion of one knee joint remained after the course of artificial fever therapy. Orthopedic manipulation (brisement force) under general anesthesia was done to separate the fibrous adhesions. Artificial fever therapy was instituted immediately following the surgical manipulation. Practically normal joint function was restored in both cases.

12 In twenty-eight patients with gonococcal infection, other than gonococcal urethritis, all evidence of gonococcal urethritis and its complications had disappeared in twenty-five (89 per cent) at the conclusion of the course of fever therapy. The remaining three patients received apparently inadequate fever therapy.

13 It would appear that the therapeutic armamentarium of the venereologist is now provided with a new and powerful weapon.

NOTICE OF EXAMINATION

An examination by the American Board of Otolaryngology of two days duration, including both written and oral tests, will be held in New York City, September 25 and 26, just prior to the meeting of the American Academy of Ophthalmology and

Otolaryngology. Prospective applicants for certificate should secure application blanks from the Secretary, Dr W. P. Wherry, 1500 Medical Arts Building, Omaha, Neb. No certificate will be granted without examination.

THE UNRULY MEMBER

We should never make the mistake of thinking that unfavorable comment on another man's work will enhance our own prestige, says Dr Delivan A. MacGregor, of Wheeling, W. Va., in a paper read before his county medical society. Usually it serves to decrease the patient's confidence in and respect for the whole profession. Speaking for myself, I confess that it took me a long time to learn this lesson. Even after twenty years of painful experience, I sometimes have an urge to tell a patient that it appears that his tonsils were gouged out with a

potato peeler, or that his operation for chronic appendicitis probably was unnecessary. How quickly the patient or his friends take the story back to the first doctor! Even if you do not actually criticize the previous work, your remarks may be distorted by the patient, who really does not understand half you say anyway, and a very unpleasant version may reach your colleague's ears. I think it is a good plan to search out something very favorable to say, if that is possible, and say it emphatically so that there may be no hint of criticism.

DETERMINING THE INDUSTRIAL NATURE OF A DERMATITIS

MARION B SULZBERGER, MD, New York City

There has been an increasing general tendency to recognize the causal connection between industrial occupations and certain skin eruptions. This tendency has been fairly accurately reflected in this country by the general broadening of the compensation laws and their interpretation. In view of the complexities and difficulties of the problems presented, it is undoubtedly true that dermatologists, and in particular dermatologists with special and specific training in industrial skin diseases, should constitute the courts of last appeal in the decision as to whether or not a given dermatosis is actually attributable to the effects of industrial exposure. In spite of this obvious desirability that the final adjudication of these moot cases be left to a board of competent and qualified dermatologists, the present system unfortunately often necessitates that such decisions be made by non-dermatologists and by lay referees, judges, and juries.

The following definition the suggested criteria for establishing the industrial nature of a given case and the description of common errors are therefore intended as a guide, not only for dermatologists but also more particularly for the general medical and lay persons who are now called upon to decide as to the industrial nature of a given skin eruption.

It seems timely to submit this material now, as New York State has recently (1935) passed a law which makes compensable all dermatoses contracted in industrial pursuits^{1,2} and as a result of this, more and more cases are daily being considered and adjudicated as of either industrial or non-industrial nature.

TABLE I—DEFINITION AND THE LIMITATIONS OF MEDICAL PROOFS

DEFINITION

Industrial Dermatitis An inflammatory skin affection in which the pursuit of an industrial occupation can be shown to be a major eliciting factor ("Industrial Dermatitis" is a subcategory of Occupational Dermatitis for Occupational Dermatitis" includes not only "Industrial Dermatitis" but also all other dermatitides attributable to any occupational pursuits and excluding those of non-industrial nature.)

PROOF

The proof of the industrial nature of a dermatitis cannot depend entirely upon medical evidence, but to a great degree also upon legal considerations. From the medical viewpoint there can be no proof absolute of the industrial nature of a given case. But there are certain medical criteria which indicate, with a high degree of probability, that a certain case of dermatitis can be considered attributable to the industrial occupation of the affected individual.

TABLE II—MEDICAL CRITERIA FOR ESTABLISHING PROOF OF THE PROBABLE INDUSTRIAL NATURE OF A GIVEN DERMATITIS

Criteria of the First Order (Indispensable criteria)

- 1 **Inception** The dermatitis appears at any time during a period of industrial exposure, or even after the lapse of a reasonable incubation period following the cessation of the industrial exposure (usually two to three weeks as a maximum)
- 2 **Amelioration** The dermatitis repeatedly disappears, or is repeatedly improved within a reasonable period after cessation of the specific industrial exposure. (While the above is usually the case, retention of causal agents, complications, or ensuing polyvalent sensitization may prolong the course even up to several years after the last industrial exposure.)
- 3 **Recurrences and exacerbations** The dermatitis shows a tendency repeatedly to recur or exacerbate when the worker returns to the identical industrial exposure after a certain period of absence (provided there has been no change in working conditions or in the individual's manner of working)

TABLE III—MEDICAL CRITERIA FOR ESTABLISHING PROOF OF THE PROBABLE INDUSTRIAL NATURE OF A GIVEN DERMATITIS

Criteria of the Second Order (Adjutant Criteria)

- 1 The dermatitis appears first in, and is usually confined to the areas of maximum exposure (in a small percentage of cases it spreads to apparently unexposed areas or even becomes generalized)
- 2 The morphe and localization of the dermatitis correspond to the morphe and localization of dermatitides known to have been caused by exposure to the same industrial hazards (While many different substances and procedures

ures can produce similar or identical eruptions, there are certain classes of substances and of procedures which regularly produce fairly characteristic lesions)

3 The application of the presumptive causal agents to an unaffected skin site close to the site of the dermatitis produces a reaction, provided this application is made either during the active phase or after an interval following the cessation of the dermatitis

4 The skin tests produce reactions of the same fundamental nature as the dermatosis under investigation

5 Other workers similarly occupied are or have been similarly affected

6 The dermatitis appears soon (days to weeks) after beginning work involving new hazards

7 The dermatitis is proven to be of possible occupational nature, that is, it is shown to be of the type which may result from the industrial exposure sustained. It must be determined that the dermatitis under consideration is not a non-industrial eruption of such dermatoses as seborrheic dermatitis, psoriasis (including pustular psoriasis), parapsoriasis, lichen planus, dermatitis herpetiformis, multiform erythema, certain types of non-industrial fungus- and other infections non-industrial impetigo and other pyodermas, acrodermatitis continua, non-occupational drug eruptions, herpetic eruptions, nevroid and other skin anomalies, non-industrial dermatitis exfoliativa, neurodermatitis, atopic dermatitis, and particularly non-industrial dermatitis venenata (It must however, be borne in mind that the presence of such a non-industrial dermatosis by no means excludes the possible co-existence of an industrial dermatitis. Moreover on the one hand, the existence of such a non-industrial dermatosis may even predispose to industrial dermatitis, and, on the other hand, industrial exposures may elicit attacks or produce exacerbations of such non-industrial dermatoses)

TABLE IV—SOME COMMON ERRORS IN THE DETERMINATION OF THE INDUSTRIAL NATURE OF A DERMATITIS

The dermatitis is erroneously considered to be industrial because —

A It is a dermatitis venenata occurring in a worker in an industry in which dermatitis venenata is known to occur (For example, such a dermatitis venenata may be due, in the specific case, to non-industrial exposures—home exposures to dyes, cosmetics, toilet articles insecticides, clothing, paint, varnishes, plants etc.—exposures to substances encountered in hobbies or avocations—photography painting sports, etc.)

B It is accompanied by a positive patch test to a substance or substances encountered in the industry

(Such a positive test cannot be considered con-

clusive, for it may be due to (1) the application of a primary irritant or of a primary irritant concentration, or (2) the fact that the test never accurately reproduces the conditions of actual industrial exposure, therefore, a positive reaction may mean simply a certain skin sensitivity to a certain substance when applied in a certain concentration and manner at a certain time to a certain site, while this same substance may nevertheless be incapable of causing dermatitis under the actual conditions of industrial exposure)

TABLE V—SOME COMMON ERRORS LEADING TO THE DECISION AS TO THE NON-INDUSTRIAL NATURE OF A DERMATITIS

The dermatitis is erroneously considered to be non-industrial because

A It is accompanied by the finding of fungi or other micro-organisms in the lesions or in a distant focus (Fungi—pathogenic and non pathogenic—and certain other micro-organisms—staphylococci, streptococci, yeasts, and moulds—are almost universally found on the skin of adults in the U S A. Their presence does not, therefore, constitute proof that a dermatosis is of non-occupational nature)

B It is accompanied by a positive reaction to extracts of fungi or of certain other micro-organisms (Such reactions are too common to be of weight in ruling out the industrial nature of a given case, these reactions merely show that the individual has had a prior sensitizing exposure to the same or to an immunologically related micro-organism—comparable to tuberculin reactions)

C The patch tests with the substances of the industrial exposure are negative

(Such negative tests cannot be considered conclusive. They may be due to (1) local differences in sensitivity. The skin area tested may be non-sensitive, while other areas, and particularly the areas involved, may be sensitive (2) Chronologic differences in sensitivity. An individual's skin, sensitive at the time of industrial contact, may be non-sensitive to the actual causal substances at the time of skin testing (3) The fact that the actual causal substance or substances, or the causal combination or causal intermediates, may not have been applied (4) The fact that the concentration employed may have been too weak, or that the test application may have been otherwise inadequate, or that the vehicle employed may have been incorrect, or may have prevented penetration, or exerted some protective or neutralizing effect (5) The fact that the test never accurately reproduces the actual conditions of industrial exposure. Repeated contact, friction maceration heat cold, sweat, etc may be necessary additional factors enabling the substance negative in the test nevertheless to cause dermatitis under conditions of industrial exposure)

The material in the above tables (I-V) is intended to apply only to cases of *dermatitis*, and not to the numerous other industrial dermatoses such as industrial acnes, industrial infections of the skin, industrial skin cancers and other tumors, industrial keratoses, and industrial skin injuries.

While I am fully aware of many inadequacies in these tables, it is nevertheless my hope that they will prove to be of some practical value. So far as I know, the information here presented has not been previously assembled in clear and concise form in any one place in the

pertinent literature. It would seem, therefore, that this tabular presentation will serve as at least a rough guide to those who are called upon to make the difficult decisions as to the industrial nature of certain dermatitides.

EX CRIPPLES WHO WON OLYMPIC MEDALS

A true story that may be helpful in preserving the morale of crippled youngsters is related in *Health Digest* as follows:

A little red schoolhouse is on fire. Children watch in awe as the flames dart out between dark billowy clouds of smoke. Suddenly, one of the boys lets out a startled cry and dashes into the midst of the blazing timbers. He had just discovered that his brother is still in there.

A few moments later he appears again at the doorway dragging his brother. Then, fearfully burned, friends carry him off.

Long hours of suffering follow. But the courage which gave him strength to dash into the inferno, carries him on to recovery. However, great streaks of scar tissue remain as horrible mementos of his valor. Every movement is painful. Even walking means torture, especially when walking to the *new* schoolhouse means a journey of several miles each day.

But the game youngster, Glenn Cunningham by name grits his teeth and *makes* the walk. Soon he finds that it is less painful to run than to walk. Later on he makes

his regular trip to school and back by *running*.

And thus is made the greatest ruler this country has ever known—made by his sheer determination to face a handicap and overcome it.

At college he becomes a star athlete acquiring medal after medal and breaking record after record, climaxing it with the establishment of the American record for the mile. Then come the Olympic games the supreme test of athletic prowess, and just last month this same ex-cripple broke the Olympic record for 1500 meters.

What a triumph for courage! What a splendid lesson in fortitude! What a fine example to all others who have some distressing defect to combat!

By the strange irony of fate, though Glenn Cunningham *did* break the Olympic record just a few short paces ahead of him was another ex-cripple, Jack Lovelock, a gallant New Zealand medical student who only three years ago, had an operation upon his knee which specialists said would prevent him from ever running again!

Truly the "will-to-win" is the one which *will* win!

BETTER CARE FOR LESS MONEY

Dr. Matthew Levitas, newly elected State Department Surgeon of the Veterans of Foreign Wars, has a proposal to save the Veterans Administration \$582,540 a year on veterans hospitalization in New York and millions throughout the United States.

The Government, Dr. Levitas said in his home in Brooklyn, could save that sum and at the same time afford the veterans better medical attention if it would cease constructing new hospitals for general medical and

surgical cases and arrange to make use of private hospital facilities for veterans' cases.

The 500,000 hospital days veterans receive at Government expense in the New York area annually, he said, cost the Veterans Administration \$4.10 a day, excluding expenses for hospital construction.

"The same services could be contracted for with private hospitals at \$3 a day, which is the rate paid by the City of New York," Dr. Levitas declared.

FAMILY PERIODIC PARALYSIS

Use of Tissue Extract

S VERNON, M D, *Willimantic, Conn*

Family periodic paralysis occurs infrequently and its rarity makes the opportunity for the study of this disease so limited that very little can be learned about it. The condition was first described by Westphal and Oppenheim in 1885 reporting one case. Goldflam later pointed out its familial character. In 1901, Singer and Goodberg reported a case, another report was made the following year by Mitchell. A report of seventeen cases was published in 1905 by Holtzapple^{1,2,3} of York, Pa. Over two hundred cases of this disease have been described to date.

Holtzapple attributed this condition to spasm of the anterior spinal artery. He pointed out that ten of his seventeen cases also suffered from migraine. He also advanced the idea that defective nitrogenous elimination was a causative factor, and that autointoxication associated with constipation, emotional excitement, and fatigue contributed to the condition.

Although several factors are distinctly suggestive of some abnormality of muscle⁴ the fact that nerve changes must occur is undeniable. The transitory character of the paralytic condition presupposes a transitory pathologic change which vascular spasm is likely to cause. The disease is characterized by extensive flaccid motor paralysis with loss of reflex and electrical excitability without sensory or psychic disturbance, and with an interval of perfect health. The disturbance is periodic and the predisposition is hereditary although sporadic cases are found. Attacks begin at any age from two to thirty, but most frequently after fifteen years of age.

Case Report

H S, age thirty-four, was admitted to the hospital under the care of Dr R L Gilman at 1 00 A M, May 8, 1933, in a paralyzed condition. Weakness of arms and legs occurred upon awaking in the morning two days before admission. He went to work but stumbled and fell during the forenoon. He drove his car home himself. In the evening weakness of extremities increased. The next morning he was

unable to move any part of his body except his head, toes, and left knee. He was unable to raise secretions in the upper respiratory tract, but was perfectly rational, conscious, and without pain. He was brought to the hospital.

First attack of paralysis occurred at the age of sixteen, patient being unable to move on awaking in the morning. Attack lasted about three days and recurred every three months for about a year. Interval between attacks increased so that he had only six attacks during the past fifteen years. Last attack occurred two years ago with a duration of five days, no loss of consciousness, no convulsions. During the past two attacks, pain in his hips occurred as muscular power returned. Lately there have been abortive attacks of weakness of arms and legs which could be worked off by exercise.

Family history. Mother, age sixty-eight, living and well. Father died of heart disease, age forty-eight. Three sisters living and well. Two brothers died in accident, another of influenza. Five other siblings died during infancy or measles, pneumonia, and other causes. No history of attacks or paralysis elicited in any relatives. Patient's mother had left hemiplegia thirty-three years ago which was treated and disappeared in one year. Patient married eleven years, wife is living and well, no pregnancies.

Past history. Normal at birth, no convulsions during infancy or childhood, had measles and chicken pox, never suffered head injury. Was severely burned in lower extremities and hips at the age of twelve. Infection and sepsis developed and was hospitalized for eight months. Complete recovery took three years.

No history of drug addiction. Changes in occupation have not altered the attacks. Present occupation is that of dyer. Patient drinks occasionally but attacks have not followed alcoholic excess. No jaundice, dyspepsia, vomiting of blood or bloody stool. Has never had chronic cough, chest pain or palpitation. Has never had dysuria, polyuria, hematuria. No change of weight in recent years.

Physical examination shows a well-developed, well-nourished man who is unable to move, having difficulty with mucus in his throat but no pain. Ears normal, neck is not stiff, teeth are carious and coated, tonsils are congested, heart negative, abdomen

negative, pulse sixty, temperature 98.6, respirations eighteen, blood pressure 110/70. Scar from burns noted on both legs. Genitalia negative, abdominal reflexes absent, right knee jerk absent, left knee jerk present, no Babinski, no ankle clonus.

Flaccid paralysis is complete for both upper limbs. Slight movement is present in right leg and ability to flex right knee and left toes is present. No change in sensation of touch, pain, or temperature in any part of the body.

Patient experienced considerable relief after suction of mucus from throat. Bladder was catheterized. Nonprotein nitrogen of blood 60 mg. Blood test 5,110,000 red blood cells, hemoglobin ninety-six per cent, 12,400 white blood cells, polynuclear cells seventy-three per cent, lymphocytes twenty-six per cent, mononuclears one per cent, Wassermann negative. Urine showed a faint trace of albumin. During the stay in the hospital muscular power of limbs gradually increased. There was some pain in the involved areas during the course of improvement. The patient regained full use and control of his muscles and was discharged two days after admission.

Follow-up

The patient was seen at home on August 3, 1934. He was found lying in bed with all extremities paralyzed. Sensation was intact but no reflexes could be elicited from the lower extremities. He was having some difficulty with raising secretions from the respiratory tract. The heart sounds were irregular in rhythm. The veins of the extremities showed irregular fusiform dilatations along their course. Paralysis continued for almost forty-eight hours and then gradually wore off, with severe pain in the lower extremities as muscular power was returning.

Patient was again seen August 14 in the morning, complaining of a "numbness" in the muscles of the lower part of the body. He was completely unable to stand erect. The arms were extremely weak, especially the right. Reflexes in legs were spastic. Sensation was normal. Two cc of tissue extract were injected intramuscularly at 9:28 A. M. Right arm felt better three minutes afterward. At 9:34 A. M., the muscle strength of the quadriceps muscles distinctly improved since patient could raise himself from a crouching posture. At 9:56 A. M., 2 cc were again administered and the patient expressed his surprise and satisfaction at the change in function that occurred and stated that he had never experienced such rapid improvement during his previous attacks. At 11 A. M., the

patient reported that he felt better and that power in his feet had completely returned. At 3 P. M., he reported that he had had a nap and was then completely normal as far as muscular activity was concerned.

On the evening of September 4, patient was again seen in an attack. His temperature was normal. He complained at this time that he had "bad breath, and a bad taste in the mouth" right after the attack similar to the taste he had experienced during attacks of fever. He also stated that a very mild attack had occurred four days previously in the morning but he managed to work it off during the day.

No reflexes could be elicited in the right leg. Left leg was weak and spastic reflexes could be elicited. Two cc of tissue extract were administered in the left thigh at 8:45 P. M. At 8:54 P. M., sufficient function returned so that he could flex the left foot although not as much power was present in the right. At 9:02 P. M., two cc were given in the right thigh. At 10 P. M., patient was able to walk about the room without assistance. The next morning, patient went to work.

The drug used here is tissue extract of the pancreas and is known to be effective in angiospastic conditions. It has been studied by Wolffe⁵ and others who found that it produced a transitory decrease in arterial tension which was attributed to vascular dilatation. It is therefore used in angina for its effect on the coronary vessels. It has been established that this substance neutralizes the pressor action of epinephrin. Adrenalin⁶ is said to be contraindicated in this disease. It is believed that the favorable effects obtained from the use of the drug in this case results from relief of spasm of the anterior spinal artery, since transitory ischemia of the anterior horn cells could produce the condition. The attacks in which the drug was used were moderate but it is apparent that improvement occurred more rapidly than in the abortive attacks. The earmarks of intestinal intoxication (feter oris and constipation) coinciding with the attacks leads to speculation concerning the casual relationship of the former. For example, tyramine, a product of decomposition and known to be present in the intestine produces sympathomimetic stimulation less powerful and more persistent than epinephrin. Bassler has suggested the possibility of intestinal toxemia being an etiologic⁸

factor in the production of nerve disease. Since glycine has been found to be effective in muscle disorders, Schoenthal suggests that it be tried in such a case to combat the myopathic⁹ factor in this condition.

Comment

In a sporadic case of family periodic paralysis, intestinal intoxication appeared to coincide with the attack. Striking re-

lief followed in two of the attacks by the use of tissue extract, a drug which relieves vascular spasm. If similar results can be obtained in other cases it would support the premise that family periodic paralysis is due to spasm of the anterior spinal artery. It appears therefore, that the agent is worthy of further trial in attacks of this disease.

LITTLE THINGS ABOUT MANY THINGS

A news dispatch from Washington says that an entirely new food and drug bill will be introduced by Senator Copeland and Representative Chapman of Kentucky at the next session of Congress. Senator Copeland said that legislative counsel for the Senate and House are now drafting such a bill "entirely independent of the Department of Agriculture."

A busy physician, Dr. Ignazius Byrne, finds no time to lead the Greenpoint Chamber of Commerce, as president, in its civic programs to secure local improvements. Now that Greenpoint has its swimming pool, Dr. Byrne is continuing the chamber's efforts to secure a much needed high school for the McCarren Park section.

A newborn child in New Zealand can look forward, on an average, to five and a half more years of life than a child just born in the United States, according to the Statistical Bulletin of the Metropolitan Life Insurance Company.

The State Medical Society of Wisconsin has restored its annual dues to the prewar level of \$15.

Investigations reveal that Japan is exporting more than ninety-eight per cent of all foreign toothbrushes shipped here. Turned out by her coolie factory labor, these brushes are scaling tariff walls and selling at a wholesale price of around 2.28 cents each.

San Francisco has a Chinese hospital now in its twelfth year. It cost \$350,000,

contributed by the Chinese, and has a typical Chinese curving roof in blue, green, red, and yellow tile. It is, however, modern and up-to-date in every detail. Its ten doctors are all American Chinese, with prominent American consulting physicians. Two of the seven graduate nurses are American Chinese. The kitchen serves American or Chinese food, as preferred.

A Scotchman had been told by his doctor that he had a floating kidney. He was much disturbed by the diagnosis and went to the Minister of his Church with a request for the prayers of the congregation.

"I don't know," said the minister dubiously. "I'm afraid that at the mention of a floating kidney the congregation would laugh."

"I don't see why they would," replied the sufferer. "It was only last Sabbath you prayed for loose livers."

ENDOCRINE STUDY OF HYPOGONADISM AND CRYPTORCHIDISM

MURRAY B. GORDON, M.D., Brooklyn

From the Department of Pediatrics, Long Island College of Medicine and Endocrine Clinics of the Long Island College Hospital and Israel Zion Hospital

The endocrine consideration and treatment of cryptorchidism was greatly stimulated by Engle¹ in 1932 when he demonstrated that in monkeys with delayed puberty, descent of the testes may be experimentally produced by injection of the active principle of the anterior pituitary gland or of pregnancy urine.

The mechanism of testicular descent in the human, according to him, is as follows:

- 1 Hormone activity is an integral part of the pituitary-gonad relationship and depends upon the normal stimulative action of the gonadotropic hormone and the normal receptive condition of the gonads. The descent of the testes at birth is due in a large measure to gonad activators present in the blood of the mother and fetus during pregnancy and in the latter in early neonatal life. Cryptorchidism ensues if the testes do not react to the stimulus of the hormone of pregnancy or if the hormone level drops at too early a period before the testes are sufficiently differentiated to respond.

- 2 Mechanical factors

- (a) The gubernaculum testis affords directive and possibly tractor influence.
- (b) The increase in the size of the testes in the inguinal canal forces them down into the scrotum especially since normally the internal ring is closed when the testes enter the canal.

With these principles in mind, the etiological factors in cryptorchidism may be one or more of the following:

- 1 Hypopituitarism producing insufficient pituitary gonadotropic stimulation. The testicular function is normal.
- 2 Primary hypogonadism resulting in insufficient reaction to pituitary stimulation.
- 3 Primary hypothyroidism resulting in lack of primary tissue differentiation and lack of testicular response.

- 4 Mechanical factors causing arrest of the testes at any point in its descent.
- 5 Late normal descent without any endocrine or mechanical disturbance.

We have found the following diagnostic points valuable in the differentiation between the thyroid and pituitary types of cryptorchidism:

- 1 The primary hypothyroid type is found in childhood myxedema and hypothyroidism. If the onset occurs during the first year of life, there is a delay in the time of teething, walking, and talking, and in the appearance of carpal centers in the wrist. Other criteria are low metabolism, high cholesterol (above 200 mg per 100 c.c. of blood), normal specific dynamic action of proteins, dry skin and hair, small thin teeth, and constipation.

- 2 The hypopituitary type occurs in association with adiposogenital dystrophy, anterior pituitary deficiency of growth and pituitary infantilism. Cryptorchidism may be the only indication of pituitary-gonad deficiency irrespective of the size of the phallus. The laboratory findings in the pituitary deficiency group are high blood uric acid (above 35 mg per 100 c.c.), high blood chlorides (above 500 mg per 100 c.c.) and absent or low specific dynamic action of proteins. The basal metabolism may be increased, normal or decreased depending upon the functional activity of the thyrotropic hormone of the anterior pituitary gland or of the thyroid hormone itself.

Because of the lack of definite information in the literature as to the incidence of cryptorchidism and hypogonadism we reviewed the records of 519 boys who had been observed in two endocrine clinics. 398 presented some endocrine disturbance and 121 did not. The following findings are interesting as they are probably the first statistics of these conditions based on a large series (Table I).

Hypogonadism and cryptorchidism occur almost twice as frequently in the endocrine group as in the nonendocrine in the pro-

This is Number VI in a Series of Endocrine Studies in Infants and Children

Read at the Annual Meeting of the Medical Society of the State of New York
New York City April 29 1936

portion of 87.5 per cent as against 33.9 per cent.

The incidence in the individual endocrine disorders in the order of greatest frequency is as follows: eunuchoidism, adiposogenital dystrophy, anterior pituitary deficiency of growth, mongolianism, hypothyroidism, and nonendocrine conditions.

Cryptorchidism occurs in the following incidence: eunuchoidism, adiposogenital dystrophy and hypothyroidism in practically the same proportion, mongolianism, nonendocrine conditions, and anterior pituitary deficiency of growth.

Hypogonadism without cryptorchidism is most frequently encountered in the following sequence: anterior pituitary deficiency, adiposogenital dystrophy, eunuchoidism, mongolianism, hypothyroidism, and nonendocrine conditions.

Scope and Material of present Study

The present communication reports the findings and results of study of hypogonadism and cryptorchidism in boys ranging in age from two to fourteen years.

There are thirty-eight cases of cryptorchidism associated with the following conditions: adiposogenital dystrophy, twenty; eunuchoidism, two; hypothyroidism, seven; anterior pituitary deficiency, one; mongolianism, one; mechanical causes, two; it occurred in otherwise normal boys in five instances. Bilateral involvement was present in twenty-three cases and unilateral in fifteen. The location of the testes was as follows: in abdomen, fourteen of bilateral, nine of unilateral type, in the canal, seven bilateral, six unilateral, one in abdomen, and one in canal in two cases of bilateral cryptorchidism. Testes of the wandering type or which could be forced into the scrotum are not

considered as true cryptorchidism and are not included. Hypoplastic genitalia were present in thirty cases out of thirty-eight.

There are thirty-six cases of hypogonadism with descended testes. The latter were practically all smaller than the normal and the scrotum varied from a small pouch with a median raphe to one of fairly normal size. The three components of the external genitalia generally showed the same tendency to underdevelopment but in many instances the scrotum was normal and the testes hypoplastic, and vice versa. Of the thirty-six cases, twenty-five occurred with adiposogenital dystrophy, seven with hypothyroidism, three with primary hypogonadism, and one with anterior pituitary deficiency of growth.

All of the patients were studied in accordance with the methods and procedure described in a previous communication.² A resume of the chemical and laboratory findings are given in Table II and indicates that the underlying endocrine disturbance in both hypogonadism and cryptorchidism is a combination of hypothyroidism and hypopituitarism.

Treatment

The treatment of cryptorchidism and hypogonadism in this series is based on the belief that both conditions are associated with deficiency of the thyroid and pituitary glands. This is confirmed by the laboratory and chemical findings in this series and by the beneficial results obtained by the empirical use for many years of thyroid extract in all hypopituitary states. The plan of treatment is as follows:

TABLE I—HYPOGONADISM AND CRYPTORCHIDISM IN ENDOCRINE AND NON-ENDOCRINE CONDITIONS

Condition	Total Number	Normal Genitalia	Hypogonadism (Testes Descended)	Cryptorchidism	
				Bilateral	Unilateral
ENDOCRINE					
A.G.D.	306	21 (6.8%)	184 (60.1%)	53 (17.4%)	48 (15.7%)
Hypothyroidism	28	13 (46.5%)	6 (21.5%)	4 (14.2%)	5 (17.8%)
Hyperthyroidism	1	1 (100%)	0 (0%)	0 (0%)	0 (0%)
Anterior Pituitary Deficiency	20	2 (10%)	15 (75%)	2 (10%)	1 (5%)
Eunuchoidism	7	0 (0%)	3 (42.9%)	3 (42.9%)	1 (14.2%)

Non-endocrine	121	66.1%	33.9%		

1 Oral administration of thyroid and anterior gland in the following dosage

	1st Month	2nd	3rd	4th
Desiccated thyroid substance	gr $\frac{3}{8}$	gr $\frac{1}{4}$	gr $\frac{1}{2}$	gr 1
Desiccated anterior pituitary substance	gr II	gr III	gr IV	gr V

This combination is increased every month as indicated and is given three times a day for the first three weeks of the month and discontinued for the fourth week. The last dose is continued with the same alternation.

2 Hypodermic injection of anterior pituitary extract, 1 c.c. twice a week. This is given in every case of hypogonadism for the entire course of treatment and for the first month or two in every case of cryptorchidism. In those cases where beneficial results are observed in the latter, the injections are continued for a longer period.

3 In all cases of cryptorchidism and in protracted cases of hypogonadism, anterior pituitary extract is changed as above to anterior pituitary-like extract (of pregnancy urine), one c.c. two to three times a week. In a few instances a combination of one c.c. each of anterior pituitary extract and pregnancy urine extract is given two to three times a week.

4 In all cases of obesity, a diet is prescribed which is low in calories (900 to 1000 a day) high in proteins, and low in fat and carbohydrates. Salt and water intake are restricted.

In six cases the oral administration of thyroid and anterior pituitary extracts was the only method used. In ten cases, hypodermic injections of anterior pituitary extract were given in addition and in twenty-two cases pregnancy urine extract was administered in addition to oral medication.

Results

Cryptorchidism The findings in Table III indicate that beneficial results in cryptorchidism may be obtained by any of the three methods used in this series. However, the combined use of thyroid and anterior pituitary extracts by mouth and extract of pregnancy urine by hypodermic injection is much more beneficial than that of thyroid and pituitary extracts alone or in conjunction with hypodermic injection of anterior pituitary extract. Complete descent was obtained in the three methods as follows. *First*, thirty-three per cent, *second*, fifty per cent, and *third* fifty-seven per cent. Results were noted with the first method in 7.3 months, with the second in six months, and the third in 3.7 months, on the average.

There were nine cases of failure in the thirty-eight cases of cryptorchidism, two were treated by the first method and seven by the third method. The types were as follows: adiposogenital dystrophy, five, mechanical, two, and cryptorchidism alone, two. In the obese group, two (2 and 12 years of age) were treated by oral administration and three (2, 5, and 8 years of age) by the addition of pregnant urine extract. One of the boys with the mechanical form is twelve years of age and had been operated upon two years previously for left inguinal hernia and left cryptorchidism. The operation for the cryptorchidism was unsuccessful. He is still under treatment and has not shown any advance of the testes in the canal after thirty injections. The second patient in this class is eight years of age and has also a left undescended testis with inguinal hernia. There has been a perceptible drop from the upper to the lower levels of the canal after one year's treatment.

An analysis of Table IV indicates that the treatment of cryptorchidism by any of the methods used in this series may be effectual at any age between two and fourteen years. Treatment is much more effective after five years of age than prior to it. There is an increasing tendency to better results with an increase in age at the onset of treatment.

There is a difference of opinion as to the functional capability of the undescended abdominal testicle. Some claim that the testes cannot develop nor function normally except in the scrotum and

that the germinal epithelia undergo degeneration elsewhere. The exocrine function of spermatogenesis and reproduction is diminished or even lost but the endocrine element is not disturbed. Against this is the statement of others that the undescended testicle before puberty is indistinguishable microscopically and macroscopically from the normal. In this series, descent of the testes was generally followed by an increase in size. In no

instance was there any sign of atrophy.

Spontaneous descent of the testes may occur in a certain percentage of uncomplicated cases between the ages of ten and fifteen years. Drake³ found in his series that there was a spontaneous descent in the majority of instances of unilateral cryptorchidism by the fourteenth year. It is not desirable, however, to postpone treatment until puberty in the hope that spontaneous descent will occur. No boy

should be subjected to an operation for undescended testicle until he has been given the benefit of organotherapy for at least six months. If bilateral cryptorchidism is still present at the age of fourteen years after a trial of endocrine therapy, then operation should be performed. The results of surgery are not very gratifying as about fifty per cent of the cases reported in the literature have been unsuccessful.⁴

Hypogonadism. Cases of hypogonadism with descended testes, especially when associated with adiposogenital dystrophy and hypothyroidism, responded in the majority of instances to oral administration of thyroid and anterior pituitary extracts and hypodermic injection of anterior pituitary extract. Extract of pregnant urine was added only in stubborn cases. Treatment in this group resulted in an increase in size of the external genitalia in twenty-eight instances and no effect in eight. The failures included five cases of adiposogenital dystrophy, two of hypothyroidism, and one of eunuchoidism. The results in each component part were not uniform, i.e. enlargement of the phallus was not always accompanied by a corresponding increase in the size of the testes or scrotum, or vice versa.

In the second group (hypogonadism with cryptorchidism) the effects on each component were also not parallel. In the thirty-eight cases in this group, thirty showed underdeveloped genitalia. The response to treatment was as follows in twenty-two where a complete or partial descent of the testes was obtained, fifteen showed improvement in the size of the phallus and seven did not. In seven instances of failure in cryptorchidism, an increase in the size of the phallus resulted in four and no effect in three instances.

The administration of anterior pituitary extract was followed in several instances by one or more of these untoward symptoms: urticaria, angioneurotic edema, pruritis, abdominal cramps, and loose bowel movements. Anterior pituitary-like extracts produced rashes and itching but no gastrointestinal symptoms. Acute congestion of the testes occurred in two instances in boys with adiposogenital dystrophy and descended testes after the injection of six and ten c.c. respectively, administered in doses of one c.c. twice a week. We did not observe any symptoms

of prostatic involvement or of glycosuria.

The extra-genital results will be discussed in detail in another communication.⁵ We may state briefly here that there was a reduction of twenty-five per cent in the overweight on a basis of comparison with Baldwin's standards of weight to height and age. There was a normal increase in stature. The basal metabolic rate and specific dynamic action were increased in the majority of instances. While there was a relationship between the general and local genital improvement, this was not along parallel mathematical lines. Improvement in the basal metabolic rate, specific dynamic action, obesity, and the general endocrine condition was generally but not always accompanied by the same degree of improvement in the hypogonadism or cryptorchidism, or vice versa.

Summary and Conclusion

Review of the records of 521 boys with endocrine or non-endocrine conditions shows that hypogonadism and cryptorchidism occur almost twice as frequently in the endocrine as in the non-endocrine group. Every child with either one of these conditions should be examined from an endocrine viewpoint. Cryptorchidism may be due to deficiency of the pituitary, thyroid or testicular glands or to non-endocrine conditions such as mechanical factors or late normal descent.

Studies on thirty-eight boys with cryptorchidism and thirty-six with hypogonadism with descended testes show on the average a hypopituitary deficiency as manifested by low basal metabolic rate, low specific dynamic action of proteins and high blood values of cholesterol, chlorides, and uric acid.

The treatment of cryptorchidism in this series is based upon the assumption that it is a symptom in the majority of instances of a disturbed hypopituitary-gonad relationship and not a clinical entity. Three methods are used:

- 1 Oral administration of thyroid and anterior pituitary extracts in increasing dosage,
- 2 Oral administration of thyroid and anterior pituitary extracts and hypodermic injection of anterior pituitary extract,
- 3 Oral administration of thyroid and anterior pituitary extracts and hypodermic injection of anterior pituitary-like (pregnant urine) extract.

Beneficial results may be obtained in cryptorchidism by any of these methods. The combined administration of anterior pituitary and thyroid extracts and hypodermic injection of pregnant urine extract is much more beneficial than the other two methods. Complete descent of the testes was obtained in the three methods as follows: *First*, thirty-three per cent, *second*, fifty per cent, *third*, fifty-seven per cent. The average length of time was in the first method, 7.3 months, in the second, six months, and in the third, 3.7 months.

We have found that the treatment of cryptorchidism by any of the methods used may be effectual at any age between two and fourteen years, but is more effective after five years. No boy should be subjected to an operation for undescended testicles until he has been given the benefit of organotherapy for at least six months.

Hypogonadism, especially when as-

sociated with adiposogenital dystrophy and hypothyroidism, responds in the majority of instances to oral administration of thyroid and anterior pituitary extracts and hypodermic injections of anterior pituitary extract. Extract of pregnant urine is necessary only in the stubborn and protracted cases.

Improvement in the basal metabolic rate, specific dynamic action, general endocrine condition, and obesity is generally but not always accompanied by the same degree of improvement in the hypogonadism and cryptorchidism. The effects on the phallus, scrotum, and testes are not parallel. Untoward effects may result from the use of either anterior pituitary or anterior pituitary-like extracts.

Discussion

DR SIMON A. BEISLER, *New York City*—The subject presented by Dr. Gordon is of interest to the practicing physician, pediatrician, endocrinologist, surgeon, and urologist. My discussion will be limited to the surgical and urological aspects tempered mainly to practical experiences and observations noted in similar cases treated in the Squier Urological Clinic.

Most observers are in agreement that normal testicular development including spermatogenesis does not occur after puberty if the testicle is outside the scrotum. At this point the factor of spontaneous descent should be taken up. It is granted that at the age of puberty or shortly thereafter a fairly large number of previously undescended testes descend into the scrotum and remain there. This occurs more frequently in the unilateral, but also occurs in bilateral undescended testes. Drake claims that this occurs in the greater number of cases, however, statistics compiled by the Army during the draft showed three in one thousand recruits with undescended testes. In practice every urologist encounters cases from both the sterility and impotency standpoint that give a history of bilateral descent after fourteen to sixteen years of age who present considerably undeveloped testes without associated endocrine pathology and for whom to date nothing can definitely be accomplished. Likewise many of the cases giving a history of descent of a previously unilateral undescended testes after puberty shows this

testicle to be undeveloped. From this standpoint it is advisable to attempt by some means to get the undescended testicle into the scrotum sometime before puberty. This raises the question as to what single or combination of procedures will best accomplish complete descent of abnormally located testes and at what age they are best carried out.

Dr. Gordon has pointed out the relative incidence of cryptorchidism and hypogonadism in a large series. We all agree they must be divided into an endocrine and non-endocrine group. He has divided his therapy into four plans of treatment. Groups 1 and 2 were treated by thyroid extract and either desiccated anterior pituitary substance by mouth or anterior pituitary extract by hypodermic, and while I am not in a position to discuss this phase of treatment his results are better than those obtained by workers using somewhat similar methods of treatment. Many claim oral administration of the anterior pituitary extract by mouth is of no value. Group 3 was treated by substituting anterior pituitary-like extract (of pregnancy urine) one cc two to three times a week with or without the addition of hypodermic injections of anterior pituitary extract. The anterior pituitary secretes two gonadotropic hormones. The one is normally found in pregnancy urine extracts and stimulates largely the connective tissue (interstitial cells) but does have effect on the seminiferous epithelium, the other is present in

HYPOGONADISM AND CRYPTORCHIDISM

Number 181

extracts of castrates and stimulates mainly the semineferous epithelium. Experimental evidence points out that the anterior pituitary secretes at least six hormones, and with this in mind as well as the fact that the present available products are usually impure physiologically, we are more than likely using admixtures of these various hormones. I have particularly in mind the thyrotropic hormone which definitely stimulates the thyroid gland, an effect it is said to lose in protracted and long treated cases.

In presenting the following similar cases, treated either as in or outdoor patients at the Squier Urological clinic, I have selected a number of earlier cases which have been followed from one to three years after cessation of all treatment. Follutein was the preparation used in our cases.

CASE 1 Age eight. Right testicle at external inguinal ring, left not palpable with an associated perineal hypospadias. The patient received one c.c. (250 rat units) twice a week for three months at which time the right testicle was in the scrotum. The left at the external inguinal ring. Treatments were continued at longer intervals for thirteen months with no change.

CASE 2 Age fifteen. Right, undescended, not felt, left in scrotum. Sixteen one c.c. intramuscular injections of Follutein three times a week. The right testicle now was at the external inguinal ring and orchidopexy was performed with an excellent end result. An associated indirect inguinal hernia was repaired, cord was not transplanted.

CASE 3 Age nine. Bilateral undescended. Right in the inguinal canal, left at internal inguinal ring. Patient received eighteen injections of one c.c. of Follutein twice weekly. Orchidopexy performed with a good end result on the right side, a poor end result on the left side. The left testicle lying at the upper end of the scrotum. Postoperative treatments by Follutein had no beneficial effect.

CASE 4 Age thirteen. Right testicle at external inguinal ring, left at internal inguinal ring. Patient received fifteen injections of Follutein one c.c. at the end of which both testes were at the external inguinal ring. Orchidopexy bilateral yielded good result.

CASE 5 Age thirteen. Left testicle in inguinal canal with associated hernia. Right in scrotum. Twelve injections of Follutein one c.c. three times a week showed testicle at abdomino-scrotal junction. Repair of hernia and orchidopexy gave good end result.

CASE 6 Age fourteen. Right undescended at internal inguinal ring, left in scrotum. Twelve one c.c. injections of Follutein given and testicle was then at the external inguinal ring. Orchidopexy with good result.

CASE 7 Age eleven. Right undescended not felt. Eighteen one c.c. doses of Follutein were given three times a week and testicle could be palpated at the external inguinal ring. Orchidopexy performed after which testicle occupied the upper scrotum. Postoperative Follutein caused no improvement. Considered poor result.

CASE 8. Age eight. Left testicle said to have been scrotal at birth but gradually receded and was at internal inguinal ring. Follutein given in one c.c. dosage three times a week for four weeks and testicle found at external inguinal. Orchidopexy performed. Testicle occupied upper scrotal region. End result considered poor. Postoperative Follutein had no beneficial effect.

CASE 9 Age fifteen. Right undescended testicle in inguinal canal with associated hernia. Six one c.c. doses of Follutein twice a week, at which time testicle was just below external inguinal ring. Orchidopexy and hernia repair without cord transplantation with excellent result.

CASES 10, 11, 12, 13, 14—Ages 16, 17, 16, 16. 20—With unilateral undescended testicles gave no response to Follutein therapy.

The above fourteen cases represented the non-endocrine group. The best results were obtained in the group from eleven to fifteen years of age. Five cases sixteen years of age to twenty gave no response to hormonal therapy.

In the endocrine group four bilateral and two unilateral undescended testes were encountered under twelve years of age and all gave and maintained complete descent on Follutein therapy with increase in size of the testicles, but as soon as the preparation was administered only once in two to four weeks they receded to their former small size but remained in the scrotum.

Work in this field has been continued in a much larger group of cases at the Squier Clinic. We definitely feel it advisable to try hormonal therapy on cases of cryptorchidism that at present hormonal therapy only will be necessary in the endocrine group particularly in the so-called Fröhlich syndrome group. That in the non-endocrine group a combination of variable doses of hormonal therapy and surgery will be required and that this should be carried out before puberty. At present I would hesitate to say at what age this is best carried out. Later after following these cases we will most likely decide this question.

I would like to recall to your attention that before hormonal therapy was introduced good results were obtained in the non-endocrine group by simple orchidopexy where possible and in those where this procedure could not be done, the Torek operation was found satisfactory. In 1927 Meyer reported one hundred per cent satisfactory results in sixty-four cases. Recently Burdick and Coley reviewed one hundred and thirty-seven cases from the Hospital for the Ruptured and Crippled and Harris in 1933 reported twenty-seven cases all with satisfactory end results. Will the Torek operation be replaced by a combination of hormonal therapy and simple orchidopexy?

Beneficial results may be obtained in cryptorchidism by any of these methods. The combined administration of anterior pituitary and thyroid extracts and hypodermic injection of pregnant urine extract is much more beneficial than the other two methods. Complete descent of the testes was obtained in the three methods as follows: *First*, thirty-three per cent, *second*, fifty per cent, *third*, fifty-seven per cent. The average length of time was in the first method, 7.3 months, in the second, six months, and in the third, 3.7 months.

We have found that the treatment of cryptorchidism by any of the methods used may be effectual at any age between two and fourteen years, but is more effective after five years. No boy should be subjected to an operation for undescended testicles until he has been given the benefit of organotherapy for at least six months.

Hypogonadism, especially when as-

sociated with adiposogenital dystrophy and hypothyroidism, responds in the majority of instances to oral administration of thyroid and anterior pituitary extracts and hypodermic injections of anterior pituitary extract. Extract of pregnant urine is necessary only in the stubborn and protracted cases.

Improvement in the basal metabolic rate, specific dynamic action, general endocrine condition, and obesity is generally but not always accompanied by the same degree of improvement in the hypogonadism and cryptorchidism. The effects on the phallus, scrotum, and testes are not parallel. Untoward effects may result from the use of either anterior pituitary or anterior pituitary-like extracts.

Discussion

DR SIMON A. BEISLER, *New York City*—The subject presented by Dr. Gordon is of interest to the practicing physician, pediatrician, endocrinologist, surgeon, and urologist. My discussion will be limited to the surgical and urological aspects tempered mainly to practical experiences and observations noted in similar cases treated in the Squier Urological Clinic.

Most observers are in agreement that normal testicular development including spermatogenesis does not occur after puberty if the testicle is outside the scrotum. At this point the factor of spontaneous descent should be taken up. It is granted that at the age of puberty or shortly thereafter a fairly large number of previously undescended testes descend into the scrotum and remain there. This occurs more frequently in the unilateral, but also occurs in bilateral undescended testes. Drake claims that this occurs in the greater number of cases, however, statistics compiled by the Army during the draft showed three in one thousand recruits with undescended testes. In practice every urologist encounters cases from both the sterility and impotency standpoint that give a history of bilateral descent after fourteen to sixteen years of age who present considerably undeveloped testes without associated endocrine pathology and for whom to date nothing can definitely be accomplished. Likewise many of the cases giving a history of descent of a previously unilateral undescended testes after puberty shows this

testicle to be undeveloped. From this standpoint it is advisable to attempt by some means to get the undescended testicle into the scrotum sometime before puberty. This raises the question as to what single or combination of procedures will best accomplish complete descent of abnormally located testes and at what age they are best carried out.

Dr. Gordon has pointed out the relative incidence of cryptorchidism and hypogonadism in a large series. We all agree they must be divided into an endocrine and non-endocrine group. He has divided his therapy into four plans of treatment. Groups 1 and 2 were treated by thyroid extract and either desiccated anterior pituitary substance by mouth or anterior pituitary extract by hypodermic, and while I am not in a position to discuss this phase of treatment his results are better than those obtained by workers using somewhat similar methods of treatment. Many claim oral administration of the anterior pituitary extract by mouth is of no value. Group 3 was treated by substituting anterior pituitary-like extract (of pregnancy urine) one cc. two to three times a week with or without the addition of hypodermic injections of anterior pituitary extract. The anterior pituitary secretes two gonadotropic hormones. The one is normally found in pregnancy urine extracts and stimulates largely the connective tissue (interstitial cells) but does have effect on the seminiferous epithelium, the other is present in

extracts of castrates and stimulates mainly the seminiferous epithelium. Experimental evidence points out that the anterior pituitary secretes at least six hormones, and with this in mind as well as the fact that the present available products are usually impure physiologically, we are more than likely using admixtures of these various hormones. I have particularly in mind the thyrotropic hormone which definitely stimulates the thyroid gland, an effect it is said to lose in protracted and long treated cases.

In presenting the following similar cases, treated either as in or outdoor patients at the Squier Urological clinic, I have selected a number of earlier cases which have been followed from one to three years after cessation of all treatment. Follutein was the preparation used in our cases.

CASE 1 Age eight. Right testicle at external inguinal ring, left not palpable with an associated perineal hypospadias. The patient received one c.c. (250 rat units) twice a week for three months at which time the right testicle was in the scrotum, the left at the external inguinal ring. Treatments were continued at longer intervals for thirteen months with no change.

CASE 2 Age fifteen. Right, undescended, not felt, left in scrotum. Sixteen one c.c. intramuscular injections of Follutein three times a week. The right testicle now was at the external inguinal ring and orchidopexy was performed with an excellent end result. An associated indirect inguinal hernia was repaired, cord was not transplanted.

CASE 3 Age nine. Bilateral undescended. Right in the inguinal canal, left at internal inguinal ring. Patient received eighteen injections of one c.c. of Follutein twice weekly. Orchidopexy performed with a good end result on the right side, a poor end result on the left side, the left testicle lying at the upper end of the scrotum. Postoperative treatments by Follutein had no beneficial effect.

CASE 4 Age thirteen. Right testicle at external inguinal ring, left at internal inguinal ring. Patient received fifteen injections of Follutein one c.c. at the end of which both testes were at the external inguinal ring. Orchidopexy bilateral yielded good result.

CASE 5 Age thirteen. Left testicle in inguinal canal with associated hernia. Right in scrotum. Twelve injections of Follutein one c.c. three times a week showed testicle at abdomino-scrotal junction. Repair of hernia and orchidopexy gave good end result.

CASE 6 Age fourteen. Right undescended at internal inguinal ring, left in scrotum. Twelve one c.c. injections of Follutein were given and testicle was then at the external inguinal ring. Orchidopexy with good result.

CASE 7 Age eleven. Right undescended not felt. Eighteen one c.c. doses of Follutein were given three times a week and testicle could be palpated at the external inguinal ring. Orchidopexy performed after which testicle occupied the upper scrotum. Postoperative Follutein caused no improvement. Considered poor result.

CASE 8 Age eight. Left testicle said to have been scrotal at birth but gradually receded and was at internal inguinal ring. Follutein given in one c.c. dosage three times a week for four weeks and testicle found at external inguinal ring. Orchidopexy performed. Testicle occupied upper scrotal region. End result considered poor. Postoperative Follutein had no beneficial effect.

CASE 9 Age fifteen. Right undescended testicle in inguinal canal with associated hernia. Six one c.c. doses of Follutein twice a week, at which time testicle was just below external inguinal ring. Orchidopexy and hernia repair without cord transplantation with excellent result.

CASES 10, 11, 12, 13, 14—Ages 16, 17, 16, 16, 20—With unilateral undescended testicles gave no response to Follutein therapy.

The above fourteen cases represented the non-endocrine group. The best results were obtained in the group from eleven to fifteen years of age. Five cases sixteen years of age to twenty gave no response to hormonal therapy.

In the endocrine group four bilateral and two unilateral undescended testes were encountered under twelve years of age and all gave and maintained complete descent on Follutein therapy with increase in size of the testicles, but as soon as the preparation was administered only once in two to four weeks, they receded to their former small size but remained in the scrotum.

Work in this field has been continued in a much larger group of cases at the Squier Clinic. We definitely feel it advisable to try hormonal therapy on cases of cryptorchidism that at present hormonal therapy only will be necessary in the endocrine group particularly in the so-called Fröhlich syndrome group. That in the non-endocrine group a combination of variable doses of hormonal therapy and surgery will be required and that this should be carried out before puberty. At present I would hesitate to say at what age this is best carried out. Later, after following these cases we will most likely decide this question.

I would like to recall to your attention that before hormonal therapy was introduced good results were obtained in the non-endocrine group by simple orchidopexy where possible, and in those, where this procedure could not be done, the Torek operation was found satisfactory. In 1927 Meyer reported one hundred per cent satisfactory results in sixty-four cases. Recently Burdick and Coley reviewed one hundred and thirty-seven cases from the Hospital for the Ruptured and Crippled and Harris in 1933 reported twenty-seven cases all with satisfactory end results. Will the Torek operation be replaced by a combination of hormonal therapy and simple orchidopexy?

ALLERGIC MANIFESTATIONS TO COWS' MILK

CHARLES GILMORE KERLEY, M D, *New York City*

While allergic reactions to cows' milk are most pronounced in the infant and young child, no age is exempt

Bret Ratner¹ divides human milk reactors into two main groups, the inherited and the acquired with emphasis on the acquired type

My clinical observation agrees with Ratner in the main but I believe that the matter of inheritance plays fundamentally a greater role than is the evident conclusion of Ratner

Sensitization to cows' milk takes place in two ways, antenatal in utero and postnatal through the gastrointestinal tract. Congenital, prenatal passive sensitization has been demonstrated by Rosenau and Anderson,² Wells,³ and others. Ratner⁴ has shown that the guinea pig fetus may be actively sensitized in utero, and has also demonstrated that active sensitization may result in the human infant by the passage of native milk proteins (lactalbumin and lactoglobulin) from the pregnant woman's blood into that of the fetal circulation. This offers an explanation for those cases of infants reacting violently when given milk for the first time. In other words they have been sensitized before birth and the apparently initial contact with milk is in reality a secondary one and the reaction is therefore allergic in nature.

Many more cases of allergic reaction to milk are seen in the young than in the adult and the reaction may be of a much greater intensity. This may be explained in part through the establishment of immunity in the adult by the processes of immunization resulting from habitual ingestion throughout the years.

In a vast number of milk reacting infants and children there is the history of milk incapacity in the parents. Milk intolerance in the adult frequently demonstrates itself in quite ordinary types of illness such as migraine, chronic colitis, habitually coated tongue and offensive breath, frequent headaches, constipation, periodic gastrointestinal crisis, chronic eczema.

I look upon allergy to milk as a familial disorder, a condition of systemic inheri-

ority, and transmissible. The wide variety in combination with the allergic manifestations can be explained through a physiologic deficiency, a pre-allergic state and in all probability of suprarenal gland origin.

Many instances could be given in which milk intolerance has been present in three or four generations among my patients.

A young woman who could not tolerate cows' milk gave birth to twins, one was allergic to cows' milk, made acutely ill by its use and was breast-fed successfully, the other was allergic to breast milk and had to be brought up on the bottle, both lived to grow up normal adults.

Four generations of milk reactors in one family occurred under my observation, a grandmother, daughter, granddaughter and great grandson.

A twenty-five year old mother, a milk reactor, first baby six months old thriving on the breast, mother's milk insufficient. Mother was advised to drink cows' milk to increase her own supply but she objected, claiming it disagreed and it had always made her more or less uncomfortable and ill. I insisted that she make an attempt. This was carried out and it was found that she could tolerate one pint a day without discomfort—not so with the baby, she developed eczema of a fairly urgent type, the mother discontinued cows' milk and the eczema cleared up. Evaporated milk was given to supplement the mother's supply, this was taken satisfactorily without skin manifestations. A further attempt was made about one month later at my suggestion for the mother again to attempt the drinking of cows' milk, simply a try-out, I was anxious to see what would happen, again the eczema appeared on the baby's cheeks, this child grew up to be a fine young woman developed hay fever at the age of fourteen years, vaccines successfully used at the age of twenty years, married at twenty-two years, promptly had twins also under my care, both reacted actively to cows' raw milk and both thrived on evaporated milk cooked one hour with starch. It is our practice in active reactors to boil the evaporated milk for one to two hours to bring about a greater desensitization.

The hypersensitiveness in the young to cows' milk has in my experience most frequently occurred in those in whom there

was a family history of milk intolerance as mentioned above. Thus hypersensitivity is shown in the most pronounced fashion through the nervous system and to a lesser degree in other systemic reactions. The many hundreds of children who have come under my observation showing conclusively a milk allergy are divided into three main groups.

Group 1—Shock through ingestion. A breast-fed five months old baby was brought to me because of an inability to take cows milk, the mother stated that the breast milk was failing, that she attempted cows milk formula and the baby was made violently ill. I discounted the mother's story and against her remonstrances placed a few drops of milk, perhaps eight or ten, on the baby's tongue. In a few moments the child passed into a condition of urgent shock, extreme pallor, shallow respirations, unconscious, heart sounds barely discernible, under urgent stimulation the child slowly came back to normal. The mother's milk largely failing, goats milk was substituted without any inconvenience to the child and he thrived satisfactorily.

A healthy normal ten months old breast-fed infant had been given small amounts of a fresh cows milk formula by the family physician to supplement the inadequate supply of breast milk, the child invariably refused and the small amount forced was immediately rejected. Again the physician directed that the mother discontinue nursing and give a cows milk formula. Two ounces was taken and retained, and in a short time the child developed alarming shock, pallor and was pulseless. The extremities were cold and the child could not be aroused, temperature was sub-normal. It was at this time that I came on the case with my associate, Dr. Gaylord Graves. One of us was in constant attendance for seventeen hours when the child died. After the ingestion of the milk the baby went into collapse and never regained consciousness.

Several shock cases have since come under my observation, cases of a lesser degree of severity. Cows milk in these was never attempted by me in any form. The wet nurse or goats milk has supplied the substitute. The symptoms complained of are the same in all, vomiting when cows milk was forced and prostration varying in degree and urgency, two of these children were seen in one family offspring of parent milk reactors. It is interesting to note that scratch skin tests to cows milk were invariably negative in the shock cases.

Group 2 relates entirely to gastrointestinal symptoms with a wide variety of

effects demonstrating the allergy, anorexia, habitual vomiting, colic periodic gastrointestinal crisis, failure to thrive without evident illness other than constipation requiring daily attention, often times alternating with diarrhea, a condition usually accompanying considerable abdominal distention. This gastrointestinal group is exceedingly large, coming from various sources and the story is very much the same. The most frequent complaint is failure to gain in weight regardless of other specific manifestations.

On examination of these patients there is absence of adipose, soft stringy muscles, incipient rickets, quite frequently secondary anemia, in short, generally undernourished, unhappy unsatisfactory infants.

Infants are never born with celiac disease, it is this group that supply the cases. This type also does not give positive protein skin reactions.

Group 3 Nutritional or gastrointestinal disturbances are not prominent here, the allergy is manifested by the skin reaction—atopic eczema, urticaria, giant hives.

The diagnosis of milk allergy in infants and children rests largely upon a clinical basis, in sixty-five cases of eczema in which scratch skin tests were carried out but five were positive to cows milk.

In spite of the negative scratch skin test the important feature of our treatment in eczemas consists in the use of evaporated milk cooked one to two hours or skimmed fresh cows milk cooked four to six hours.

It would seem from a clinical angle that skimmed cows milk cooked several hours supplies in many cases the best desensitized milk product for use in the eczema infant.

The presence of fat either interferes with the desensitizing process or adds an element that bears on the production of the eczema.

Since my experience with the shock cases through ingestion, I have not had the courage to try the intradermal method. This is borne out by the case reported by Ratner⁵ who tried the intradermal test with pure lactalbumin in a shock type of case under carefully controlled conditions, this child manifested a prompt shock reaction but recovered.

Postnatal milk allergy may develop at any period of infancy and childhood, and is explained by Ratner¹ as follows:

- 1 By isolated feedings of raw cows milk given to the breast-fed infant during the newborn period.

- 2 By giving raw cows milk during convalescence from disease and during and after gastrointestinal disturbances.

- 3 By the use of excessive and exclusive milk diets.

- 4 By the use of injections of milk from non-specific therapy.

Infants and young children showing clinical cows milk sensitization have been coming to me in increasing number during the past few years, with but few exceptions these patients have been fed full strength raw cows milk at a tender age together with other food substances unsuitable for the life period. The story is one of the overfed thriving infant, the family joy until trouble arises. The above feeding practice is probably the most successful way of producing a milk allergy in the individual.

Many cases of mucus colitis (chronic type) in runabouts and older children have been demonstrated due to a cows milk allergy through withdrawing the milk absolutely from the diet and substituting a desensitized cows milk product (calcium caseinate) sold under the trade name of Casec and made by Mead Johnson.

The studies on the basic principles of the treatment of milk allergy by Ratner¹ bears out my many years of experience. He has shown that the heat labile elements in the milk (lactalbumin and

lactaglobulin) are responsible for practically all cases of milk allergy for which reason they are successfully treated with some form of heat or chemically denatured milk. I have long advocated their use.⁶

Summary

The object of this contribution is to emphasize the importance of milk allergy and show how widespread are the manifestations that may result from such hypersensitiveness. The case of death that I report is very similar to the one reported by Finkelstein many years ago and should serve as a warning to all physicians who may be dealing with a shock milk reactor.

A MEDICAL COUNCIL FOR BIRTH CONTROL

Formation of the National Medical Council on Birth Control to "initiate, encourage and execute appropriate scientific research in the medical aspects of birth control" was announced recently by the American Birth Control League, 515 Madison Avenue, New York City. The council is composed of seventy-one physicians in twenty-three States.

The announcement said the new group also would control and supervise all medical policies of the league, replacing a smaller

medical advisory board.

Dr Frederick C Holden, Emeritus Professor of Obstetrics and Gynecology, New York University College of Medicine, is chairman of the council's executive committee. Other members include Dr Foster Kennedy, Dr Eric M Matsner, Dr Edgar Mayer, Dr Richard N Pierson, Dr Wilbur Ward, Dr Eliot Bishop, Dr Ira S Wile, Dr William H Cary, Dr Robert L Dickinson, Dr John F Erdmann, Dr Sophia J Kleegman, and Dr Raymond Squier.

PAIN A LIFESAVER

"It's just too bad that tuberculosis doesn't hurt," declared a well known specialist just a few days ago. This remark set me to thinking, and the more I think of it, the more I am impressed with its wisdom.

When we realize that it is pain, not the diseased appendix, that drives the patient to the physician, often just in time to save the life of the patient, we are apt to be more inclined to recognize pain as a "blessing in disguise."

Diseases that cause no pain until they are far advanced, such as tuberculosis, cancer, pneumonia and heart disturbances, are apt to have a high rate of disability, or death, according to their several natures. Where pain is an early symptom of disease the physician is sought early in the course of the disease. As a rule the more painful the symptom, the better the chance of a cure, because help is more apt to be sought early.—L E Smith, M.D., *Bulletin of the Kentucky Dept of Health*

stead of spinach and cod liver oil"—*Illinois Medical Journal*

SELECTIVE OLEOTHORAX

CHARLES E HAMILTON, M D, *Brooklyn*

Chief Attending Physician, Division of Tuberculosis, Kings County Hospital

and

EMIL ROTHSTEIN, M D, *Brooklyn*

Junior Attending Physician

Oleothorax is one of the more recently introduced and less commonly utilized methods of collapse therapy in the treatment of pulmonary tuberculosis. It consists of the injection into the pleural space of varying amounts of oil, as a replacement of air or pus, for one of several purposes which are not satisfactorily fulfilled by artificial pneumothorax.

E D, white female, aged forty, of Irish descent, first became ill during the winter of 1932-1933 with cough and expectoration, loss of weight, anorexia, and night sweats. The ailment was diagnosed as pulmonary tuberculosis, and this was confirmed by examination, roentgenography, and sputum examinations. The pathology was shown by x-ray at this time to consist of tuberculous infiltrations involving both the right upper and left lower lobes. The patient was then

kept on modified bed-rest for about two years, with little improvement.

Upon admission to Kings County Hospital, June 6, 1934, she complained of cough, expectoration, night sweats, chills, and fever. Examination and x-ray study revealed a tuberculous process affecting chiefly the right upper lobe, with a major cavity about six cm in diameter, and tuberculous infiltrations through the lower portion of the left lower lung field, of a fibrotic character (Fig 1). The sputum was repeatedly positive for the tubercle bacillus.

Pneumothorax therapy was started June 12. A free pleural space was found and refills were given twice weekly. After two months had elapsed the major cavity was considerably decreased in size, however the patient still suffered from her original symptoms and the sputum was positive. At

Fig 1 Entry to hospital. Large cavity is seen in the right upper lobe. Pleural thickening on the right. Fibrotic changes on the left.

Fig 2. After eight weeks of pneumothorax. Left unchanged. Right presents cavity smaller but patent. Adherent bands seen, especially one very broad one traversing the right chest.

this time it was seen that the right pleural space was traversed by numerous adhesions and adhesive bands (Fig 1), which radiated in all directions from the cavity. We felt at this time that they would prevent any further collapse of the cavity. In addition the patient was becoming more dyspneic due to the displacement of the heart and mediastinum to the left. The adhesions were considered too formidable for the Jacobus procedure. In lieu of a more satisfactory procedure the pneumothorax was continued

Fig 3 After fluid collection is present. Cavity much smaller

An x-ray taken August 24 revealed an unusual and unexpected finding (Fig 3). There had developed, as is common during the course of artificial pneumothorax, a pleural effusion. Due, however, to the broad adhesive band seen in Fig 2 the pleural space had been divided into two almost completely separated compartments. A large portion of the effusion had collected in the upper of these two partitions and by its direct compression had collapsed the cavity to less than one-tenth of its original size.

At this time several questions came up in considering further therapy. It was felt that if pneumothorax were continued in the usual manner the fluid would be absorbed, with reopening of the cavity. If, on the other hand, repeated attempts were to be made to enter the upper pocket, difficulty would soon be encountered as the pocket was small and in a rather inaccessible posi-

tion, since the walls of the pocket were composed of thickened pleura and many adhesions were present, it was believed that these factors would also lead to an obliteration of the pocket with re-expansion of the cavity. It was decided to inject oil into the pocket, with the purpose of introducing with a few injections a substance which would not be absorbed for many months.

On September 2 with two needles in the second right anterior interspace, 100 c.c. of one per cent gomenol in olive oil were

Fig 4 Shortly before discharge. The upper pocket is filled with fluid and oil. The cavity is no longer visible. Left is unchanged. Moderate effusion in the main pleural cavity

injected. A slight rise in temperature and right chest pain followed, both of which subsided within ten days. Many subsequent x-rays were taken, all revealed the pocket completely filled with oil and fluid (Fig 4). On none of the subsequent films could the cavity be visualized. The patient's condition from this time showed progressive improvement, temperature, pulse, and respirations became and remained normal. Anorexia, night sweats, and lassitude disappeared and cough and expectoration became reduced to an insignificant amount. Numerous sputum examinations, including several twenty-four hour concentration tests were negative for bacilli. She was discharged to her home under medical supervision December 21. On several visits to the hospital during the ensuing five months there was no change in her condition.

Discussion

In performing oleothorax, as a rule, one of two oils is used, mineral oil or olive oil. There is little to choose between them as each will be irritating to the pleura in a certain number of cases. It is said that mineral oil is absorbed more slowly. Very commonly gomenol is added to the oil to be injected. Gomenol is a resinous product with antiseptic properties. The concentration used varies from ten per cent in virulent empyemas to one per cent in noninfected cases.

Oleothorax has several major indications. Probably the most important is in the treatment of the postpneumothorax empyemas, where the pus is removed and replaced with oil at intervals of from one to several weeks. Second to its use in empyema, oleothorax is of use in the treatment of a re-expanding pneumothorax lung which can

no longer be kept collapsed by the use of air. Here the technic consists of replacing the air with oil. The rationale is based upon the very slight absorbability of oil as compared with air.

In the present case the use was based upon this latter principle. The unusual division of the pleural space into two almost independent pockets, together with the development of an effusion in the upper of these, with cavity closure, represented a fortuitous grouping of circumstances, and oleothorax seemed the only possibility of arriving at a satisfactory therapeutic result, with the exception of major surgery. Inasmuch as only a small oleothorax was produced instead of a complete one, which was selective over the diseased area, this type of oleothorax might properly be designated as selective oleothorax.

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B. LIBER, M.D., D.R.P.H., *New York City*

Editorial Note: Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine.

Alice in Wonderland

Here is a case of slight maladjustment in a child, but interesting because of its simplicity.

A boy of five walks in alone into the hospital clinic. He speaks fearlessly. "I had ice cream!"

My immediate conclusion is that such an event is not very frequent for him. And looking at his clothes I see that he is living in poor circumstances.

I ask him

"Where is your mother?"

"Mother will come in soon."

"What is your name?"

"Siegfried."

"Second name?"

"Giant, Siegfried Giant."

"Do you have brothers and sisters?"

"Yes, I have Alice."

He answers clearly, loud, correctly.

"Her real name is Alice in Wonderland."

"Is that so? Other sisters?"

"Yes, Alice."

"Is that all?"

"Oh, Yes, I have Minerva and my cousin Gretchen."

He repeats Alice in Wonderland several times. Apparently he likes her. Then he asks me

"What's your name?"

"Ben."

"Ben? And I have Doodoo. But where is my mother?"

"Is Doodoo your brother?"

No reply. His mother, a woman of about thirty, comes in. She had listened to our conversation from the outside and says

"There is nobody with that name. He didn't give you his true name and he has no sisters or brothers. They are all fictitious names from stories that he had heard. He gave the name Alice in Wonderland to a neighbor's little girl. She is his friend and he loves her. There is certainly something the matter with him. He is a problem child. He is a great problem and a puzzle to me. I am afraid he is going crazy. Please, Doctor, do something!"

The parents live separately.

"His father is also like that," she adds, "a neer-do-well, a dreamer, unable to make a living. He comes to see the child, but lately rarely, I don't let him."

The mother works and the child is boarding with a woman who has children of her own with whom he gets along very well.

It seems it was the kindergarten teacher who suggested that the boy be "psycho-analyzed."

The family history is negative. The child has had the measles but has been well otherwise. He is in ordinary health. Mentally he is rather superior. Among all the questions he fails to give only one answer correctly, that is his name. But he does that purposely, because he hates the old

name and has adopted a new one

The mother is attentive as he is made to point out his limbs, his head, his back, and so on, as he is shown familiar objects and pictures, as he is asked to repeat numbers and sentences. He knows who is a man, who is a woman, a boy or a girl.

He is cooperative. When told to take off his shoe, he does it properly. He also puts it on, except for tying the knot, which he has never been taught.

With chalk on the blackboard he draws a face quite acceptably. But suddenly he exclaims "I'll make snow!" And with great enthusiasm he scatters many white dots on the board.

At this point the mother stops him. "I am ashamed of you! You see, doctor, I am right. Isn't it insane?"

Then I give the child a toy—a box on which the head of a girl is painted, and containing a pencil, a penholder, and a small ruler. He grabs it and yells "Mother, the doctor gave this to Alice in Wonderland!"

At which she remarks "This shows he is not smart. You gave the toy to him."

She is unable to see that this is but a perfectly direct and childish logic. He is sure to present the box to his beloved Alice

in Wonderland, therefore it means to him that I have given it to her.

One little incident which sounds like an anecdote, but which cannot be held against this lovely child, incites the mother again to prove to me his "lack of intelligence."

At a given moment he is counting his fingers, his eyes, his ears—correctly.

He shows both ears saying "one, two, right, left."

I ask him "What do you do with your ears?"

"I count 'em," he replies at once.

This was only a misunderstanding.

When leaving he comes closer to me.

"Doctor, I wanna kiss you."

This is a contemplative child, full of imagination. He is far ahead of his mother. She is entirely incapable of appreciating his poetry, his seriousness, and sincerity while constantly acting and playing. His great mistake is his superiority. Fortunately, so far she has not succeeded in destroying it.

It is impossible to make prophecies, but some of the greatest men have been regarded as mentally inferior in their childhood and as "nuts" in their youth.

All this was subsequently explained to the mother.

Tangles

A young woman of twenty-four, single, occupied as an office clerk during the day and continuing some studies in an evening school, complained of being embarrassed "when meeting anybody" and of being unable to speak or recite in public, that is in the class room. Referred by one of her professors, to whom she told her difficulties.

"For the past eight years I have been contending with adverse conditions and with a distortion of my mental faculties. There are extreme nervous seizures of self-consciousness."

There were also ideas of persecution and, as their natural concomitant, some ideas of greatness.

Her background was most interesting and unusual.

Both her father and mother were Jewish, but her father died a few months before patient was born and, within a short time, her mother married a Christian Swede who accepted the baby as his own. Patient's name, therefore, was typically Swedish, something that would not have bothered any ordinary person, but which constantly filled this girl with remorse and made her unhappy, especially because, on account of that, she had received favors which would have been closed to her as a Jewess. She had also been brought up as a Christian and, while going, as a habit, every Sunday

to church, she felt uneasy as if she were an imposter. About eight years before she discovered that her mother was a common prostitute who used her earnings for the upkeep of the family, as her Swedish husband, dead since, had been ill and incapacitated from work for a long time. Patient was certain that all her friends disdained her because they suspected her mother.

There were hundreds of other details resulting from this unpleasant situation and from the paranoid mentality of this patient. But I shall not mention them.

Our conversations had to be frank and outspoken. They succeeded in giving our patient a new philosophy of life, in enabling her to face her problems squarely and to overcome most of them within a few months. After two weeks she wrote "I believe that I begin to see the light, although it is still hard to traverse the way out. I mean I am having a hard time training myself, but it is worth while."

She soon launched into sociability, dared to do some of the things which previously had been completely taboo to her and she proved to be interesting, bright, and successful. She cannot be said to be cured, but she is able to live with a slight mental handicap, which emerges only from time to time and which she has learned to suppress.

Labor and Social Security

In the recent adoption of its program on social security the State Federation of Labor wisely did not include in its scheme any mention of compulsory health insurance. We doubt that this was an oversight. Rather would we think it a deliberately studied and intentional omission.

We commend the omission. Labor knows that compulsory health insurance was nowhere proposed abroad as an effort to improve the level of living for the workingman. It was, on the other hand, and still is, one of the factors in the production of cheaper labor for the industrialists, because into the consideration of the costs of labor must go the cost of the laborer's production. The money the laborer spends for medical care necessarily must be reckoned into this account. Hence to produce cheaper labor, give him less wages and provide him as cheaply as possible with some sort of medical service!

The costs of the service the laborer must bear in having a deduction made from his pay envelope, and in addition, by paying the indirect and hidden taxes to cover the costs of the bureaucracy which represents the government's share in the scheme. Finally, the inevitable rise in the cost of the things the laborer buys, because the employer passes on his share

of the tax burden by increasing the price of the manufactured article by just that much, leaves the laborer with a smaller pay envelope to meet a higher price level for most of the things he is wont to buy. The result—the laborer is forced to live on a lower living level.

Labor in our country is not stupid,—usually. It has won for itself a steady improvement in its living environment and standards. Notwithstanding propagandists, labor is too hard-headed to be argued into less wages and lower living standards in exchange for compulsory health insurance which, upon study and comparative analysis of its results in countries which have it, and those which have not adopted it, appears unable to compete with the quality and character of private medical practice as we know it in our country.

Cooperation from Understanding

In spite of the many points at which law and medicine touch, there has been little organized cooperation between the two professions to secure common aims. In New York City the Society of Medical Jurisprudence has succeeded in bringing an understanding of mutual problems to a small group of metropolitan doctors and lawyers. This association is however almost unique in its field. For the most part the legal and medical professions go their separate ways, oblivious or indiffer-

ent to the benefits to be derived from closer contact

There are many legislative questions arising each year in which medicine and the law have a lively if indirect interest. Anything tending to restrict the intellectual independence or responsibility of either is of direct concern to the other. In many respects the liberal professions not only stand apart from but run counter to the commercial currents of the times. They are not governed by the concepts of industry and they cannot employ the same weapons to defend their interests. Only by making common cause and presenting a united front to aggressors can they successfully resist the growing tendency to regiment and undermine the economic security of professional life.

There are individual, concrete advantages to closer cooperation between medicine and the law. A greater familiarity with statutory obligations would prevent many physicians from becoming embroiled in malpractice actions. Conversely a better understanding of medicine would keep attorneys from precipitating unwarranted litigation and aid in the management of just cases. Combination of the forces of justice and health should work to the public benefit too.

Certainly there is nothing to be lost by closer collaboration between medicine and the law, and much to be gained. The matter is well worthy of further consideration by both professions.

The Acid Test

Books and magazine articles by lay authors continue an abundant propaganda to impress the public with the alleged benefits of compulsory health insurance. A supposedly conclusive argument for American adoption of this system is drawn from the fact that no European nation has discarded obligatory prepayment for sickness after experience with its operation. The propagandists carefully avoid any comparisons between the conditions which preceded compulsory health insurance in Europe and existing stand-

ards of medical care in the United States. Almost any system would have been an advance over the low grade contract practice from which the English workman, for example, suffered prior to the adoption of compulsory health insurance. However, the much vaunted improvements of the panel system are still inferior to the average level of medical service in the United States.

The lay advocates of compulsory health insurance make the mistake of substituting quantitative for qualitative standards of medical care. If there is any conclusive gauge of the efficacy of a system of medical service, it is furnished by vital statistics. The accurate and impartial figures compiled by the League of Nations for the period from 1911 to 1934 make out a far better case for private practice than for obligatory prepayment. Not only were death rates generally lower in the uninsured nations but preventive measures were more universal and apparently more effective. In not one respect measurable by statistics rather than prejudice did the countries with compulsory health insurance equal the showing of those whose citizens rely chiefly on private practice to supply their medical needs.

The question of costs is another aspect of compulsory health insurance that has not been treated with complete frankness by its advocates. The small sum usually cited as the worker's contribution is far from telling the whole story. So far none of those urging obligatory prepayment as a boon to labor has attempted to figure out what the latter would pay in indirect taxation and increased living costs in addition to the prescribed deductions from wages.

The Hearing Aid

It is not beyond the memory of the present generation of physicians when only the medical profession was permitted to examine the eyes and prescribe for their treatment. Today it is no longer illegal for the registered optometrist to examine and dispense lenses for the correction of impaired vision. This he does

without making a diagnosis of the cause for the faulty eyesight.

A further encroachment upon medical practice is the insidious advertising of the various concerns which manufacture aids for the hard of hearing patient. Nothing is mentioned in their advertising material which would make the reader aware of the fact that deafness is the result of many conditions, nor is it stressed that not all types of deafness are benefited by the use of an artificial hearing aid. The purpose of the manufacturers is to attract business, but, in a large sense, this is not in conformity with sound public policy. It is not fair to sell an instrument to a deafened individual who will not be benefited by its use.

The knowledge of whether or not a hearing appliance will help an afflicted individual can be determined by an otologist and his advice should be sought before an aid is bought. In the case of the indigent, hospitals and organizations such as the League for the Hard of Hearing are available for such expert service. In any event the advertising of hearing aids directly to the public with no statement to the effect that they will not help in all cases should be forbidden as misleading. The manufacturers themselves can do a great deal of public good if they would refuse to sell an appliance except on the recommendation of a physician.

Protamine Insulin

One of the problems in the treatment of diabetes has been the control of the wide fluctuations of blood sugar which are noted at different times during the day. Insulin in itself cannot do this because of its rapid action. Hagedorn's isolation of protamine from the sperm of the trout which when added to insulin forms protamine insulin, now affords the clinician with a means whereby the insulin will be absorbed slowly over a period of time.

Administered subcutaneously this new compound is slowly broken down in the tissues and the insulin is liberated into the blood stream in even, small doses. It cannot be used intravenously and, because

of its slow action, should not be given in diabetic coma. Insulin reactions following its use are more apt to make their appearance gradually and so afford more time in which to feed carbohydrates so as to counteract the impending shock.

The clinical data obtained from the use of protamine insulin is still more or less experimental in nature. The milder the diabetes, the better the control with this type of therapy. Winnett¹ feels that its use over a longer period of time and under various conditions will be required before exact knowledge of its values and action will be available.

CURRENT COMMENT

"* * * 'PLANNED SECURITY' is the prerogative of convicts and slaves, it could never have produced the breed that discovered and colonized and enriched America * * * Governmental paternalism, protecting the weak, not only from the strong but from the results of their own weakness and folly and idleness and thriftlessness, can be but a wholesale creator and preserver of these qualities. This applies even to old-age and unemployment insurance—to engaging that the man who does not save will be supplied out of the savings of others, and that the man who does not work shall be supported by the man who does. If you want to insure work, insure work, and not rewards for not working, or for doing unnecessary work lazily and badly. It ought not to be more difficult to keep industry going at a pace that will provide jobs than to provide a dole at the expense of an industry that is not going * * *

"We talk of 'social security', there is not a conspicuously good and useful citizen in America today who is not being threatened and harassed almost to the point of defection. I don't mean only captains of industry. I mean doctors and tradesmen and skilled artisans, every man-jack of us who has won his office or shop, who has a dollar in money, life insurance, stocks, bonds, mortgages, or credits. Before we heard of the More Abundant Life, we had pretty definite ideas of honor, integrity, industry and thrift. We knew what we were doing, and where we were going. Now, nobody could be found wise and brave enough to back a bet either way. Nobody dares hazard a guess as to what will happen next. * * * The rights of minorities are derided and assailed, we are surrounded by spies, and tax devisors and

To the Editor

I understand that the editors of the N Y STATE JOURNAL OF MEDICINE "endeavor to publish only that which is authentic", and therefore, I take the liberty of attracting your attention to the following, which I found in the July 15 issue of the JOURNAL, p 1032, under the title, "What is Certified Milk?", (last paragraph) Quoting "Certified milk is more nutritious per pound than a pound of steak" According to tables published by the U S Dept of Agriculture, I find that porterhouse steak has a food value, per pound, of 1270 calories, sirloin steak, 1130 calories, tenderloin steak 1330 calories, while whole milk has a value of only 325 calories per pound

Such distortion of facts is outrageous and should not be allowed in a scientific magazine

Very truly yours,
J VICTOR DONNET, M D

To the Editor

About the thirteenth of August while I

was on my way back from England a man giving the name of Mr Robert McGraw opened an account with the Columbus Branch of the Chase National Bank with a check on a Springfield, Massachusetts bank The man at that time said that he was a buyer for a firm in Springfield, Massachusetts He later cashed checks at the Hotel Monterey, Asbury Park in small amounts and a few days later attempted to buy a suit of clothes at a tailoring establishment on Broadway New York, near the vicinity of the Columbus Branch of the Chase National Bank. Subsequently, he has evidently traveled through southern New England and New York State, apparently going west

He is described as a man about five feet eleven in height weighing approximately two hundred pounds

Hotels and clothing establishments might seem to be the most usual victims but probably professional men should be on their guard also

Very sincerely yours,
ROBERT B MCGRAW, M D

HEADQUARTERS SEVENTH CORPS AREA
Office of the Surgeon

Omaha, Nebraska,
August 12 1936

Surg 353 OR (Mayo Foundation) JRH 4000
Subject Medico-Military Inactive Duty Training, Mayo Foundation
To Medical Department Reserve Officers

1 The eighth annual training course for Medical Department Reservists of the Army and Navy will be held at the Mayo Foundation, Rochester Minnesota, from October 4 to 17, 1936

2 This training course was first inaugurated by the Seventh Corps Area at the request of the Mayo Foundation to give training in military medicine to the younger medical men connected with the Foundation Other reserve officers requested permission to enroll and to take advantage of the opportunity to attend clinical presentations during the morning hours Such permission was granted and such attendance has become so increasingly popular that it is now necessary to limit the enrollment

3 The program will follow the plan of

the past years The morning hours will be devoted entirely to professional work in special clinics and study groups Officers in attendance may select the course they wish to follow from the wide variety of presentations offered The afternoons and evenings will be devoted to a medico-military program under the direction of the Surgeon of the Seventh Corps Area (Army) and the Surgeon of the Ninth Naval District (Navy)

4 This training is on an inactive duty status and is without expense to the Government Enrollment is open to all Army and Navy reservists of the Medical Departments in good standing Application should be submitted to the Surgeon of the Seventh Corps Area, Omaha Nebraska or the Surgeon, Ninth Naval District Great Lakes, Illinois Enrollment is limited to two hundred

5 The Surgeons General of the Army, Navy, and Public Health Service have signified their desire to attend at least a portion of the course

For the comfort of those who suffer from diabetes, let it be known that very great progress in the knowledge of this disease has been made in the last decade and a half. A large part of the credit for this is due to American investigators, and the discovery of insulin by Banting and Best has lessened the dangers and the ravages of the disease. The life of the diabetic has already been greatly prolonged—particularly that of the young diabetic, and it is the opinion of most students in the field, that cases properly treated should not die of the diabetes. Notwithstanding this assertion, statistics inform us that the mortality from diabetes is on the increase. However, this strange discrepancy can be adequately accounted for, and should not be construed as a cause for pessimism. It is due in part to the fact that neither the public nor the profession are fully informed on the subject. It indicates also very definitely that further education is necessary. The contributory causes of diabetes, which I mentioned before, should be properly understood and heeded—particularly by those who by virtue of race or heredity are particularly predisposed to it.

When we realize that the outstanding feature of the disease is loss of sugar in the urine, it becomes immediately clear that the body is thus deprived of its principal nutrient, and varying degrees of sugar starvation occur. The body must have sugar for sustenance. Without it, tissue waste and degenerative changes in various organs take place. The greatest damage occurs in the blood vessels. The arteries of various organs may become so affected in diabetes, that a number of very serious complications, such as defective vision or complete blindness, injury to the heart, and gangrene of the legs often ensue.

As stated, the disease is most frequent in middle age. The earlier it occurs the more severe it is. In children it is sharp in its onset, and violent in its course, and if *untreated* leads promptly to acidosis, coma and death. Conversely, the later it appears, the milder usually is its course, but, there is no case so mild, that it cannot become suddenly aggravated. Many incidents are capable of causing this change. The commonest cause is infection. The older diabetic is particularly prone to infections. His skin is dry, scaly, and is easily broken. His circulation is poor, because of the changes in the blood vessels. His tissues are undernourished—and their resistance to injury and infection is greatly reduced. All infections must be properly cared for, no matter how trivial they may

appear to be.

In view of the fact that excellent methods of treatment have been developed, disregard or neglect of diabetes at any period of life is unpardonable. Many of the ill effects can be obviated by timely intervention. Usually the symptoms of diabetes can be readily cleared up, and a state of health closely approaching the normal, re-established. These facts should be made known to the public by education. Experience has shown that the best means of safeguarding health is by prevention or early recognition of the disease. People should be made to understand the nature of the disease, how it is acquired, and the best way of preventing and treating it.

Those who are in good health but in whose family a history of diabetes exists, will do well to undergo a periodic examination by a physician. In this way the diabetic prospect can be forewarned, the predisposing causes eliminated, and the disease actually controlled in its earliest stages. Too much cannot be said on this score.

Those who now suffer from diabetes should know that we possess at present only two well-established methods of treatment—namely diet and insulin. Some patients do well on diet alone, others require both diet and insulin. Any fear of insulin is entirely unwarranted when its use is properly regulated. It is not a drug. It is not habit-forming, and may be discontinued when, and if, it is no longer necessary.

Insulin is indispensable in acidosis and coma. Formerly operations on diabetics often terminated in acidosis, coma and death. Insulin has removed this hazard, and now, even the most serious operation may be undertaken without any fear of this danger. Moreover, other reliable remedies for diabetes are *not* available now. Credulous persons who read advertisements are often seriously misled into trying other methods of treatment which appear simpler—but with disastrous results.

The diabetic patient ordinarily goes first to his private physician—the general practitioner, for advice. Diabetes is one of the few diseases capable of accurate scientific control, and every physician should be qualified to treat it. Indifference, neglect or carelessness in its management should not be tolerated. The diabetic has a right to demand of the physician the utmost competency in the care of this disease. He should be given complete instructions to guide him. Many of the tragic consequences resulting from ignorance or neglect are avoidable.

The diabetic patient certainly has no cause for despair now. The medical profession possesses the necessary means to make his

WHAT THE COMMUNITY SHOULD KNOW ABOUT DIABETES

ALBERT A. EPSTEIN, M D, *New York City*

Clinical Professor of Medicine, New York University College of Medicine

Diabetes or sugar-disease is a very large subject—and with the time allotted, it is possible to speak only of a few of the more important points, which deserve public attention.

Sugar is the chief source of energy in the body, it is the fuel which provides heat and power. Most of the food we eat is converted into sugar. This is true not only of the bread, sweets, fruit and vegetables we eat, but meat, cheese, eggs, and butter also contribute their share of sugar.

Every part of the body requires sugar for sustenance. For that reason a certain amount of sugar is always present in the blood. In the healthy individual, the sugar is used up completely and none is excreted in the urine. The ability of the body to consume the sugar usefully is believed to be due to the presence in the blood of a substance derived from the pancreas. This substance is known as insulin.

Under certain conditions the body loses the ability to use sugar in the manner stated. Consequently the sugar accumulates in the blood, and, when it exceeds a certain level, is excreted by the kidneys in the urine. If the rise in the blood sugar persists, the sugar excretion in the urine continues and the nutrition of the body becomes undermined. This is the sum and substance of the disease known as diabetes.

Since the body cannot use sugar in diabetes properly, and continues to lose it in the urine, it virtually starves—starves for the sugar which it cannot use. As a result of this condition, the affected individual experiences certain symptoms, such as hunger, thirst, itching of the skin, loss of weight, and weakness. Some cases do not develop these symptoms and the disease is discovered only in the course of a casual medical examination. In most cases, however, these symptoms develop early, and may be so distressing as to cause many to seek medical advice promptly. In persons who are less observant, less cautious of their health, these symptoms may go

unheeded. Blissfully ignorant of their danger, they try to appease their growing appetite by eating more—only to make their condition worse.

As the loss of sugar in the urine rises, the nutrition of the body suffers more and more, and certain poisonous substances develop which appear in the blood and the urine. These substances are acid in nature, and they produce a condition known as acidosis. Acidosis is very dangerous because it ultimately causes unconsciousness or coma, which eventually leads to death.

This is the course the disease pursues in most untreated cases. In young people and children, diabetes often develops very suddenly, and progresses with great rapidity. The appearance of the symptoms referred to, particularly in children, should not be ignored—and medical advice should be sought without delay.

Diabetes is believed to be due to a decrease in the amount of insulin secreted by the pancreas, or to its failure to act in a normal way. It seems probable that the other glands in the body also play a part in the disturbance.

However, just what causes the disease in one person and not in another, is not known to us, but we do know the conditions which favor its development. They are in brief *race, heredity, obesity, over-eating, lack of exercise, and emotional instability*. Heredity is undoubtedly the most important of these. While certain races of people seem to be more predisposed to diabetes than others, the environment as well as dietary and other habits alter racial predisposition. This is supported by the fact that even such races of people who do not ordinarily develop diabetes on their native soil, do so when they live in a strange environment, and acquire the customs and the dietary habits of the new environment.

Diabetes is most common in the middle period of life. It is more prevalent in women than in men—and in this result child-birth, overweight, and the propensity

With the onset of pain most patients imagine that they need a movement of the bowels, a "cleaning out" as they so often state, and they rush to the bottle of salts, calomel or the dose of castor oil. All purgatives are harmful and attain no purpose except the aggravation of the disease. A celebrated surgeon once said, "purgation means peritonitis and peritonitis means death." The lack of a free movement of the bowels does not cause acute abdominal pain. The promiscuous taking of laxatives or purgative medicine of any sort in colics or other distresses in the belly, is the cause of thousands of deaths each year. Such increase the movements of the intestine and favor perforation. If a man has an inflamed hand he does not swing it around and bump it against obstacles. He puts it in a sling and keeps it quiet. The same analogy holds true with the bowels in the vicinity of the appendix.

There is a common idea that an ice-bag relieves appendicitis, freezes it out. Such is erroneous. The cold of ice applied to the abdomen does not reach the appendix, because the skin, fat, and muscles act as insulators. This is scientifically a fact. Cold only numbs the nerves and lessens pain, gives a false security, and has no basic action on the progressing inflammation in the appendix or the occurrence of perforation.

The use of opiates, such as paregoric or "cholera mixture" is more rational but here a false security is attained and the symptoms masked obscuring the diagnosis. The physician cannot possibly have an intelligent view of the case, if the patient has been stupefied and his symptoms deadened by opiates.

The ideal course for the patient to follow who suffers from acute abdominal pain is to get to bed, take no food or water, no purgatives or even an enema and send for his physician. An enema acts about twenty-five per cent on the movement of the intestines as compared to a purgative and hence had best be avoided until ordered by the physician.

The patient may feel that this advice is too restricted but he should realize that his life may be at stake, that death from appendicitis occurs from delay and from the use of purgatives, and that death is entirely unnecessary in most cases. Only a skilled physician can say whether an acute abdominal pain is a transient trifling disorder or due to acute appendicitis.

Acute appendicitis in a sense is a public health problem. Even more than cancer appendicitis needs research studies which will aid in reducing its incidence. Until

this is done the profession does, and the lay public should, realize that there is no treatment for acute appendicitis except removal of the appendix before the infection has passed from the appendix to the peritoneum and caused the highly fatal peritonitis. In a fair percentage of cases the attack theoretically may be tided over, but who can tell early which cases will subside and which will progress to perforation and peritonitis? When sufficient symptoms are present to make a diagnosis of appendicitis the case is sufficiently serious to necessitate prompt operation.

The mortality figures of the United States show a death incidence of about twenty thousand persons each year. Statistics from the clinics of many surgeons show a negligible death rate in those cases where the infection is confined to the appendix, a high death rate when spreading peritonitis has occurred. Ordinarily the disease is easy to diagnose, only occasionally will the symptoms be obscure and in such cases the patient who has not a good doctor is simply out of luck.

Another point and an important one to the average patient, is the time element. Operation in the early stage rarely requires drainage and the patient's stay in the hospital rarely exceeds two weeks. Cases with abscess or peritonitis often need drainage necessitating a prolonged stay with painful dressings. This point is of economic importance because of the increased cost of hospital and medical care.

Ordinarily in deciding upon operation certain factors are considered relative to the general condition of the patient, but in an acute disease such as appendicitis the danger of the disease itself is paramount and except in unusual circumstances such things as a supposed "weak heart," fear of anesthesia, the presence of a cold and so on, are of little importance. Modern surgery knows how to take care of these things and safeguard the patient.

One final word, the family physician is the patient's best friend, and he will not precipitate an operation without cause. If he sends the patient to a surgeon the latter knows whether or not an operation should be performed at once or delayed for some hours while treatment is instituted to improve resistance. The surgeon is concerned with his mortality figure and while this may sound a bit cold-blooded, yet in the long run it works to the best interest of the patient. The combination of an early diagnosis and a prompt operation is the ideal and if such was a universal procedure few would die from acute appendicitis.

life happy and useful. I am not in accord with those who take a pessimistic view of diabetes, who delight in distorted mortality statistics, make gloomy predictions, and spread the gospel of fear among the sick and well alike. The methods available to us render the disease amenable to treatment, nay, more, there are many indications that we may still go beyond that point. All the avenues of approach to the problems of treatment have not been traversed. Our knowledge is steadily advancing—and we

confidently hope that a method will finally be evolved, which will not only restore the diabetic to a normal state of health but cure the underlying cause responsible for the disease. The public should know all about diabetes, but it should not be alarmed or misled by unwarranted statements.

The diabetic patient should follow the doctor's guidance but the doctor must be prepared to guide his patient properly.

DEATH FROM ACUTE APPENDICITIS

GEORGE P. MULLER, M.D., *Philadelphia, Pa.*

Professor of Surgery, Graduate School of Medicine, University of Pennsylvania

Acute appendicitis is the number one operation in all surgical clinics. It is the number one public health surgical enemy. Nearly twenty thousand young adults at an average of twenty-eight years, die each year in the United States from this disease and the pity of it is that most of these deaths might have been prevented.

Appendicitis is an inflammation of the vermiform appendix caused by micro-organisms just as acute tonsillitis is caused by micro-organisms. The appendix is a tube about three inches long hanging dependent from the cecum, the first part of the colon, and situated in the lower right quarter of the abdomen. Under certain conditions the proper drainage of this tube is obstructed, infection takes hold, and the appendix becomes swollen and inflamed.

Under certain conditions again this tube may perforate and the infectious material gain access to the peritoneal cavity causing the disease called peritonitis. It is not clear just why the infection occurs at a particular time but it seems to take hold when resistance is low and when infection such as influenza and the common cold are common. The quality of a meal is unimportant and yet most patients blame a particular food for the onset of the affection. Acute enteritis from food poisoning is a different condition and easily recognized by the physician. The patient complains of violent abdominal pain with immediate vomiting and early diarrhea. Certain other phenomena are entirely absent. This is important because most patients are prone to blame a particular article of diet for the onset of the abdominal pain.

What then are the symptoms of appendicitis in its incipient and acute forms? In the order of their occurrence and importance they are (1) pain (2) nausea and vomiting (3) rigid muscles. Later there will be tenderness, slight fever, slightly in-

creased pulse rate, and a rising percentage of white cells in the blood.

Pain is the first and foremost symptom, and any young adult with acute abdominal pain should suspect that he might have acute appendicitis. This pain is like a "colic" and at first may be in the epigastrium or around the navel. In a few hours it tends to localize in the right lower quadrant of the abdomen and at this time the tenderness in this location and the rigidity of the muscles become more apparent. Vomiting is not always present but nausea usually occurs. Any rise of temperature is important because in the earlier hours fever rarely accompanies the conditions simulating appendicitis. Under such circumstances the intelligent patient will consult his physician who will be able to differentiate the symptoms from conditions simulating appendicitis and by an examination of the blood, determine the resistance of the patient to infection.

I have noted that most patients have the onset symptoms during the night and it is important that they insist upon an early visit by their physician. In a certain percentage of cases violent symptoms are followed in a few hours by the relief of pain and this is of ominous and not favorable import because rupture of the appendix may be followed by a period of relief before the symptoms of a spreading peritonitis make their appearance.

The patient should not wait for symptoms to become sufficiently serious to indicate the necessity for prompt operation. No one except an experienced physician can tell whether or not the appendix has ruptured or is on the verge of rupture. Cessation of pain is no criterion because the tenderness, the rigidity, temperature, pulse rate, and the leukocyte count, must be taken into account.

system which *predisposes* him to stuttering

Parental neuroticism plays a significant part in the instability of the stutter-type. By "parental neuroticism" we mean a chronic state of nervous irritability, tension and anxiety. We all know the parent who is irritable, who scolds and nags, placing a burden on the nerves of a sensitive child. Thus handicapped by an inheritance from a parent emotionally unstable, and an environment colored by parental neuroticism, the child is reared in a definitely detrimental environment—a whirlpool of agitation.

Although we are far from understanding emotional balance, there is evidence that it depends on a corresponding balance in the functioning of two nerve systems which appear to check each other—the parasympathetic nervous system slowing certain activities, and the sympathetic nervous system quickening them. Normally the parasympathetic remains in dominance for the maintenance of routine functions. The sympathetic dominance is a nervous status called out by special strong stimuli, "jacking up" the organism in emergencies. Normal adjustment to environment calls for organization at both levels, without predominance of one or the other except at its proper time.

In the case of the stutterer, however, heredity and environment incline him toward a dominance of parasympathetic influence, so that he is more or less unprepared for those emergencies which necessitate sympathetic nerve control. When an emergency arises, his sympathetic nervous system does not take over complete dominance and he cannot remain organized under its influence. There is a conflict, due to his tendency to remain on the parasympathetic or slow system. Even in ordinary circumstances, when the stutterer should be on the parasympathetic plane, his fears create uncalled for emergencies which bring out a spasmodic sympathetic nerve activity, manifesting itself in the various hesitations and spasmodic muscular movements.

Many children are prone to overstimulation, so that they literally wear themselves out by their incessant talk, losing control of the mechanism of the vocal tract, with resulting hesitations. The pre-school stutter-type child with his neuropathic diathesis—that is, his nervous predisposition—has more difficulty in learning speech than other children, due to a lower grade of expression or psychomotor efficiency, with its accompanying functional disturbances. Mothers wonder why some children outgrow these manifestations and speak normally, while in others the trouble persists.

Children vary markedly in the vulnera-

bility of the speech apparatus. A mechanical disability and poor habit formation does not allow their speech to develop normally. It does not become a flexed conditioned reflex. Aside from this, no doubt there is inherently greater difficulty in surmounting environmental stress, mental unrest, with its anxiety, worry and fear.

The uneven sex distribution of stutterers lends support to our view. About eight times as many boys as girls stutter. There are many reasons for that. Aside from the fact that fundamentally there is a decided difference between male and female, especially in the makeup of the female nervous system, we must take into consideration that early environmental stress is never as hard on girls as on boys. The element of competition enters into the life of young boys much more decisively than in that of girls. Boys' games are more strenuous than girls'. The injudicious shielding of the boy by the mother who centers her affection on him further weakens him, so that he is unable to cope with environmental onslaughts. This anxious protective zeal is not beneficial but detrimental to the boy.

Besides this, since speech is the result of practice, girls being more loquacious, their speech facility is not disturbed so readily. And since they possess a finer nervous mechanism, a higher rhythmic sense, better coordination, and a higher progressive trend, it follows that they are less liable to lose their standard of organization under new environmental conditions.

When treating a stutterer, one must consider the whole personality of the individual. The reorganization of the stutter-type, therefore, cannot be brought about through temporary measures of distraction from his defect. His rehabilitation is a complex health problem of a medical-social nature, for only through a composite therapy can adaptation be brought about.

We have found that the type of treatment carried out in a medical-social clinic is a powerful motivating force for the integration of the stutter-type personality. In the course of constructive psychological analysis, potentialities long inhibited are released. In a specially created environment, through a composite therapy of a medical, psychiatric, re-educational, and social nature, the chronic hesitator learns to act harmoniously, in an organized and confident manner, and acquires a standard of emotional stability. He not only gets tranquilized, but learns to keep tranquilized.

Thus, out of anxiety and chaos comes order and peace, and with it normal speech—a fulfillment of the wish of every stutterer.

STUTTERING AND THE STUTTER-TYPE PERSONALITY

JAMES SONNETT GREENE, M D, *New York City*

Medical Director of the National Hospital for Speech Disorders

Stuttering is not synonymous with stammering although they are often used interchangeably. Stammering stands for defective articulation depending on performance, while stuttering stands for hesitant speech with resultant defective conversation, depending on certain states of mind in the form of emotions, feelings or attitudes.

Stuttering speech is one of the many manifestations of the stutter-type. This special type personality is readily recognized. Personality is expressed through the medium of one's nervous system. The type of personality which one presents to the world depends largely on whether his nervous capacity for response to the impacts of his environment is strong, weak or moderately strong. The stutter-type, on account of his nervous constitution, forms part of the group of strongly excitable individuals, whose uncontrolled reactions disturb their mental and physical activity.

The stutter-type is a chronic hesitator, coming from neuropathic stock, demonstrating neuropathic tendencies. This means that he has an inborn liability, an hereditary tendency, to nervous instability. Although intellectually and physically he is up to par, his emotional instability makes a rationally ordered life impossible, and results in a disintegrated personality.

In this stutter-type group are individuals who hesitate in more ways than in speech. Their motor-overflow shows itself in hesitating technical performance. For instance, there are those who stutter playing the piano or violin, others who make the type-writer stutter, and others who demonstrate their hesitation in such acts as dancing, golfing, driving an automobile, etc. I am sure everyone has observed stuttering automobiles, the driver imparting his own spasms to the operation of the machine.

Likewise a stutterer, when emotionally aroused, may impart spasms, so that his speech is often characterized by tonic and clonic spasms of the vocal tract. However, no matter what form his hesitations may take, it does not alter the fact that he is a stutterer.

Many theories have been advanced to explain the difficulties of the stutter-type. The conception we advance stresses the role played by primitive emotional reactions, especially fear and allied emotional states, setting off the tendency to many hesitating acts. This is particularly so in such a symp-

tom as stuttering. It is the neurotic mechanism, converting the psychic conflict into the physical symptom—stuttering.

Emotion is a strong feeling or an aroused state. There is a normal range of emotion between that of mere neutrality and a state of "pleasant excitement." When a crisis calls out a surge of emotion, the stutter type, unlike the non stutter-type, has less equilibrium to start with and also lacks practice in meeting his difficulties. Therefore, his emotions have a tendency to establish a violent and uncontrollable wrought-up condition. This characterizes the stutter-type personality, in whom the emotional turmoil of recurrent speech crises has become chronic.

Speech, our most complex, finely balanced muscular activity, is easily upset during periods of intense emotion. Many nerve areas and muscle groups, both large and small, must work in perfect harmony. Now when an individual is in a storm of conflicting emotions, lines of communications are broken, and the misdirected nerve messages become delayed or diverted into spasmodic contractions. Most of us at some time or other have experienced the distinctly unpleasant condition of loss of speech due to emotional turmoil. If we realize that the stutterer is in just such a state many times a day, our fundamental problem becomes clear.

The stutterer, although he lacks a well-trained neuromuscular organization, in his aroused state constantly tries to produce the split-second response that he sees in the normal speaker. If he cannot produce speech spontaneously, he often flies into a panic, which further demoralizes his speech faculties. He therefore unloads his surplus motor overflow in various ways—peculiar bodily movements, spasms of the musculatures involved in speech, tenseness throughout the body, and a general feeling of unbearable anxiety culminating in fear—and thus a vicious cycle is instituted.

A general predisposition toward emotional instability can be traced in the families of the stutter-type. Last year our survey of over a thousand patients showed forty per cent had stutterers in their immediate family, and over one-half gave a definite family history of nervous instability. A child, therefore, does not necessarily inherit stuttering, but belongs to the stutter-type and inherits a general instability of the nervous

Hereditary tendencies express themselves in many ways. Some can be helped if discovered early and correctly treated, others can be retarded but, in a few nothing can be done to postpone the advancing darkness.

Poor vision may be the effect of occupation.

The retina, the seeing layer of the eye, may be separated from its base either by growth beneath it, progressive near-sightedness, or a blow on the eye. The patient becomes conscious that a portion of his field of vision is absent or that a floating cloud partially covers his sight. If the detachment is the result of a tumor, the eye must be removed. If it is the result of a stretching or a tearing of the retina, it is susceptible to treatment by the use of special electric currents.

General diseases cause poor sight. In scarlet fever the patient may have kidney complications which will cause retinal disease. In diphtheria there may be a temporary paralysis of the focusing muscle making reading impossible in diabetes, hemorrhage, an instability of the focusing power, and a curious optic nerve affection which causes marked reduction in central vision.

In tuberculosis of the bones and general body structures, there may be an actual destruction of parts of the eye. Pulmonary tuberculosis, however, rarely causes a severe eye lesion. Syphilis causes failing vision in both the inherited and acquired types. Brain tumor is often first discovered by the eye specialist.

Prolonged close application is best performed under correct illumination. Campaigns for better lighting are most heartily endorsed but we cannot sanction the too-enthusiastic statements that such measures will eliminate either the need of spectacles or reduce the incidence of eye disease.

And, finally, to the disciples of health, the advocates of physical fitness, and the guardians of both, the physician, I urge an aggressive campaign for the prevention of ocular disease by its early recognition and efficient treatment with an urgent insistence that those who need glasses wear them to preserve their sight.

I leave a word of cheer to those with cataract, a message of hope to those with glaucoma, and an admonition of caution to those predisposed to circulatory diseases.

WHAT THE COMMUNITY SHOULD KNOW ABOUT SURGERY

CHAS. GORDON HEYD, B.A., M.D., F.A.C.S., *New York City*

Director of Surgery, New York Post-Graduate Hospital

Surgery at the time of the Roman emperors attained a high degree of perfection. Surgical instruments in particular were highly specialized, as is evidenced by the finding of over two hundred specimens in Pompeii. Surgical instrumentation developed under the Romans as the result of war injuries and gladiatorial combats, and occasionally from the dissection of executed criminals.

From the time of the Romans to the beginning of the sixteenth century no great progress was made in the knowledge of the human body. During the Middle Ages learning was the exclusive property of the Church and the clergy were forbidden to shed blood or to dissect the body. These prohibitions left the practice of surgery entirely in the hands of the so-called barbers—questionable gentlemen with bold spirits utterly unscrupulous, brazen, clever and with deft fingers. They were restricted by no code of ethics, had no social responsibility, and believed that bleeding was a cure-all for every ill.

In all of Europe at this time there was scarcely a score of trained surgeons. In the latter part of the twelfth century there was founded the College of Surgeons of

St. Côme, which from its inception waged a constant war against the barber surgeons. In 1515 the College became a Department of the University of Paris, and surgeons who studied in this school wore long robes and black hats, in contrast to the barbers who wore short robes. Later the short-robed barbers were forbidden to practice surgery without being examined by the school authorities.

Eighteen years after the discovery of America, Ambroise Pare, the creator of modern surgery, was born. He was, ironically enough, the son of a barber. At nineteen he became surgeon to Francis I, took a degree from the University of Paris as Master Barber Surgeon and served under four kings of France. He was a man of great attributes: an acute observer, a philosopher, a diligent recorder of his experiences and a man of great humanity. He raised surgery to a profession and a science.

Paré re-discovered the ligature for tying off blood vessels. He refrained from cauterization of wounds with red-hot irons. He covered them with a bland ointment, and observed that these individuals recovered more quickly and with less pain than those

WHAT THE COMMUNITY SHOULD KNOW ABOUT FAILING EYESIGHT

ARTHUR J BEDELL, M D, *Albany*

Attending Ophthalmologist, St Peter's Hospital

Immutable unrelenting time leaves its marks on the human body as it does on all other living things

When the average person reaches the age of forty, a change takes place in his eyes, a dislike to do near work, a late afternoon or early morning headache, a tendency to hold small objects farther away, and occasionally blurred vision. Correctly fitted glasses permit close application with clear sight and without discomfort. The testing for glasses is a highly technical art and the one prescribing lenses must also be competent to render an opinion on the general health of the patient.

A complete examination includes the study of the background of the eye, the stage upon which many of the tragedies of life are enacted. It is now possible to make a photographic record which is of extreme value, for, by it the past, the present, and the future ocular health can be told.

If a patient has to change his glasses frequently, it is an indication of either a constitutional or local eye disease and calls for a searching investigation.

Widely heralded special forms of glasses have an extremely limited range of usefulness. Telescopic lenses and contact glasses are for rare conditions and will never take the place of properly fitted spectacles.

One frequent cause of failing vision is cataract. This is a clouding of the lens of the eye and may be of an isolated part, slowly progress, start and stop or rapidly involve the entire structure. Babies may be born with cataracts and children may develop them during the course of their growth, especially when undernourished. Some cataracts mature in a very short time, as for instance in diabetes and goiter. Others follow the ingestion of dinitrophenol, a drug which has an unwarranted reputation as a safe cure for obesity.

In some families cataracts appear early in life, in others, late. If the sight is poor the cataract can be removed. After the operation serviceable vision is usually restored. The majority of those who have cataracts wear proper glasses and live without fear or apprehension of the future.

By means of a special instrument, the slitlamp, it is possible to tell whether a cataract will grow rapidly or change so slowly that for years there may be scarcely any perceptible advance. I would be dere-

lict in my duty if I failed to have you understand that no form of medical treatment has ever changed the course of a senile cataract, no drug, no serum, nothing.

Glaucoma is a hardening of the eyeball. It is of such sinister force and such wide distribution that everyone should know about its manifestations. In one form there is redness of the eye accompanied by sudden loss of sight, pain, nausea, vomiting, and the symptoms of a gastrointestinal upset. If seen early and an operation properly performed, sight is frequently recovered.

The other type is unaccompanied by redness or pain but, like a thief in the night, it steals sight by gradual encroachment on the field until only the central vision remains. It is one of the most perplexing of eye diseases and calls for the best in ophthalmoscopic diagnosis and therapeutic skill. If patients are placed under treatment before the field of vision, the ability to see about, is much reduced, glaucoma can be checked.

When a patient has transitory attacks of blurred vision, he should immediately consult an eye specialist.

High blood-pressure is an example of foreordination or predestination for heredity plays the principal role in its production, onset, and course. One form is, however, preventable, that which develops in the course of pregnancy. The ophthalmologist is the one most competent to advise when the fetus should be removed for he is able to recognize the premonitory signs of approaching disaster. High blood-pressure is often diagnosed by the ophthalmologist in his routine examination of the eyes.

If we admit that man is as old as his arteries, then heredity and his physical and mental condition determines the time when poor vision will result from circulatory disease. A particular type of arteriosclerosis involves the minute blood vessels which supply the center of sight. Those afflicted are unable to read but they can see things about them and never go blind.

Pernicious habits produce poor sight. The near-sighted child who persists in reading in the dark corners of a room, the patient who uses alcohol or tobacco to excess, and the fair one who wishes to remove superfluous hair, by drugs, are all drifting on a treacherous sea where the uncharted rocks which lead to blindness are hidden from view.

WHAT THE COMMUNITY SHOULD KNOW ABOUT INFANTILE PARALYSIS

LOUIS C SCHROEDER, M D, *New York City*
Attending Pediatrician, New York Hospital

Not a single one of the communicable diseases strikes as much terror in the hearts of fathers and mothers as does infantile paralysis. The deadly fear thus engendered is unfortunate, because it tends to break down that wholehearted cooperation and morale which must exist among parents, physicians, and public health officials, a co-operation which is especially necessary during an epidemic. Probably the most important fact which the public must know, not only about infantile paralysis but about all the communicable diseases, is that early recognition and prompt reporting of cases to the proper health authorities are the most important steps in making effective control possible.

The first of these steps is largely in the hands of the public. Parents and teachers especially will find it incumbent upon them to seek medical aid whenever there is the slightest suspicion of disease. Once competent medical aid is sought, the second step, that of reporting, will naturally follow. The more prompt the recognition and reporting, the greater are the chances of stamping out an epidemic, or at least of limiting its ravages.

The isolation of those ill and the quarantine of those who have been in contact with the sick are procedures which succeed only as an educated and enlightened public demands that they be carried out to the last detail.

If one mother in a community, who because of a fanatical belief in some metaphysical system of healing or because she accepts a neighbor's diagnosis, permits her slightly ailing youngster to mingle with other children, she may be responsible for starting a chain of cases which it may be impossible to break before many are crippled or, even worse, dead. Isolation and quarantine are scientific measures deserving of the undivided and wholehearted support of the entire community. In no disease are they more necessary than in infantile paralysis.

What is this disease, which, since the turn of the century, has invaded the New York area in three epidemics and has appeared elsewhere in our country with varying frequency and severity? This scourge of childhood and, less frequently, of adults is an infectious disease caused by a virus. A virus is a micro-organism so small that the most powerful microscopes have failed

to bring it into the range of human vision. Like many infections, the first symptoms come on quickly. These usually are fever, headache, vomiting, constipation, diarrhea or sore throat. Unfortunately the early symptoms do not help us very much because they are those seen in the infections of the respiratory or of the gastrointestinal tract. If, however, there is added as an early symptom a marked objection to being touched or handled and stiffness of the neck or back, the chances of it being infantile paralysis are much greater. Occasionally tremors of different muscle groups are seen, and pain which may vary much in severity, is present in a large percentage of cases. If paralysis does develop, it seldom occurs before the second or third day, and may even be delayed as late as the twelfth day.

The sources of all infections are human carriers and the patients themselves. The disease is transmitted by direct contact with infected persons, which must include those who are carriers of the virus, or indirectly by contact with fresh discharges from the nose, throat, or bowels of those same individuals. There is some evidence to support the theory that it may be spread by milk, but it is quite generally agreed that this is unusual and infrequent, and can be avoided if the milk is pasteurized or boiled.

From the time the virus enters the person affected until it begins to manifest its presence is ordinarily from seven to fourteen days. This is known as the period of incubation. It is not known conclusively when a person who has been infected becomes capable of transmitting the disease, but this probably occurs rather early in the incubation period and lasts at least through the first week of the disease. Because nobody is absolutely certain how long the virus remains active in the nose and throat or possibly in discharges from the intestinal tract it is not possible to give the exact length of time that isolation or quarantine should be maintained. However, it is practically certain that a patient who is kept three weeks in isolation will not be a source of danger. All children who have been exposed to a direct case and all adults, who are food handlers, should be kept in quarantine for a similar period.

Newborn babies are apt to receive immunity from their mothers but this almost always disappears by the end of the first

Read by Dr Walter P. Anderton, Director Medical Service, Knickerbocker Hospital

treated with hot irons. Thus was re-introduced to the practice of surgery the recognition of the great reparative powers of nature, so wisely extolled and exploited by the Greeks. This new era in surgical physiology has become fixed in medical history by Paré's famous expression, "I dressed him, God healed him."

For surgery to progress it was necessary to understand the various manifestations of surgical disease. This great development of surgical knowledge came from England where John Hunter, a born truth seeker, became the founder of surgical pathology. Specimens of the major surgical conditions were obtained and studied, and their safeguarding resulted in the Hunterian Museum in London.

With the names of Paré and John Hunter comes Lister, and interposed is Louis Pasteur, who developed the theory of germs as the causation in disease. Before Lister's time every surgical wound was naturally supposed to be accompanied by pus. If the pus did not flow freely it was a dangerous sign, whereas a copious discharge was considered a sign of healing and called "laudable pus." In 1867 began the story of antiseptics and absorbable ligatures. Lister and Pasteur together established the bacterial or germ theory of disease. Under the genius and personal influence of these three men—Paré, Hunter, and Lord Lister, the three greatest surgeons of all time—modern surgery was created.

During all this slow developmental period three outstanding thoughts were present in the minds of thinking physicians, and it was upon these three factors that modern surgery was created. The first was the elimination of pain, the second, the control of hemorrhage, and the third, the prevention of infection. Until these three basic conditions were met there could be no scientific surgery, although in 1809 McDowell in Kentucky had successfully performed a major abdominal operation.

Pain can be eliminated by producing anesthesia, or the pain itself may be obliterated while the patient remains fully conscious. Modern chemistry has developed a surprisingly large number of substances capable of producing anesthesia. We have local anesthesia where chemicals are injected in or about the area of the operation, and we have chemicals that can be injected into the veins and produce unconsciousness and elimination of pain. We may inject chemicals into the spinal canal and rectum, and accomplish the same purpose. We may have the patient inhale gas of many kinds and different qualities, and we have the classical anesthetic agents—ether—and rarely, chloroform. Again in the prevention

of infection we have chemical materials such as Tr of Iodine for sterilizing the skin and others for the instruments, or better still, simply boiling them. We have developed complex sterilization apparatus that sterilizes all the gauze, bandages, and drapings that are in contact with a patient during an operation. We have discovered antiseptic sera and drugs for the prevention of infection. The control of bleeding was accomplished by the discovery of the method of tying up blood vessels with silk twine and later with catgut, an absorbable material made from the intestines of sheep. By the proper application of these three outstanding fundamental conceptions it has been possible for surgeons to operate upon every area of the body, to enter into every cavity, even the heart and brain, with safety.

From the beginning of time individuals have been injured, and with great loss of blood. Many diseased conditions are associated with a similar loss of blood, and there arose the idea of transplanting in whole or in part the blood from animals or from other human beings to the sick or wounded individual. Today the operation of blood transfusion has reached a plane of absolute precision and, where indicated, great effectiveness. The introduction of a syringe into a vein of the arm of the donor and the transference of the blood into the sick individual would seem a very simple procedure. Yet in that performance there were a number of difficulties to be overcome. In the first place, the blood of various individuals was not compatible, and in overcoming this incompatibility many physicians, physiologists, and chemists were concerned. As a result of their observations and research there are four main blood groups, and generally speaking the blood of one group can be transfused into an individual of the same group, but not otherwise. The second difficulty to be overcome was that blood outside of the blood vessels "clots" in four to six minutes. To prevent this, the operation of transfusion carries the blood from the donor to the patient so rapidly that clotting does not occur.

What is the lesson to the community to be derived from these facts? It is that every invention and every discovery in the arts and sciences, if useful in the practice of surgery, is utilized. Every major discovery contributes to the usefulness of modern surgery. Every hospital contributes in teaching and in research. Every medical school and every physician also shares in making possible two factors in the safety campaign for healthful living. To make the patient safe for modern surgery, and to make modern surgery safe for the patient.

tremely small germ, so minute that it cannot be seen even with the aid of the most powerful microscope. This type of germ is scientifically known as a filterable virus. When it gains entrance to the human body it most frequently causes an inflammation of the back of the nose and throat, the larynx, and the trachea. The common symptoms of this inflammation are running nose, sneezing, sore throat, hoarseness, and cough. The acute stage of the disease usually lasts from three to five days and is generally not accompanied by fever of any degree. The symptoms of the infection, however, may frequently persist for from two weeks to a month. This continuance of the disease beyond the acute phase is commonly caused by what is termed secondary infection. Most healthy people carry in their throats, particularly during the winter months, a variety of germs that are potentially harmful. In addition to these, other disease-producing bacteria are acquired from time to time by contact with strange individuals particularly in crowds, due to the fact that germ-containing particles of the secretions of the nose and throat are expelled into the air during the process of talking or coughing. These newly acquired germs survive for varying periods of time in their new environment. Under the influence of the inflammatory process set up by the cold, these two types of bacteria contribute their injurious effects to the diseased tissues and aggravate and prolong the infection. In fact, the common complications of the cold such as sinusitis, and bronchitis, and inflammation of the cavity of the ear in children, are commonly due to such bacteria. In short, the inflammatory process in the common cold is initiated by a filterable virus which is specific, but the disease is prolonged and complications are produced by the common germs carried in the mouth or by those acquired from close contact with other people.

It is obvious that if science could bring the upper respiratory infections within the sphere of effective public health control, great benefit would accrue to humanity. In attempting to solve a problem of this kind, it is important to examine the succession of events which attends outbreaks of the disease under investigation and to attempt to break this chain of circumstances at its weakest link. The discovery, that intestinal infections are generally spread through the medium of contaminated water and food, and the control of the purity of those necessities has led to the practical disappearance in highly organized communities of such former scourges as cholera and dysentery. Here it has been possible in a relatively

simple manner to check the disease in question by breaking the line of communication. In general this is the most direct approach to the problem of the control of infectious disease. Unfortunately, the common cold is spread from individual to individual by the necessary and continuous contacts of human life. Public health authorities have suggested a number of important procedures, such as, staying at home during the acute stages of the cold, avoiding close contacts in crowded places, and protecting others from infectious secretions by covering up sneezes and coughs, but owing to the frequency of the disease and the limited disability which it causes, the methods recommended are seldom adequately carried out by the public. The fact that the cold is communicable to others by contact for at least as long as five days makes it unlikely that isolation can be practiced for so long a period of time except perhaps in the case of children. Furthermore, efforts to control the disease by attempting to develop and apply a successful form of treatment have proved disappointing. Experience of the past has taught us that once an infection is established in the human body only rarely can it be cured by medical means. This fact has led public health men to expect more benefit from preventive than from curative measures.

The failure of such public health measures as are applicable today, adequately to control the spread of respiratory infections, has led investigators to explore the possibilities of more highly specialized methods. Among these one of the most important is that of preventive inoculation or vaccination. Such a procedure has been successfully and extensively used in the control of smallpox. In order to apply such a method with any hope of success it is necessary to know the causative agent of the disease in question, and furthermore it must be possible to grow this agent in the laboratory in large quantities and in a sufficiently simple manner for general application. In the last few years both of these requirements have been met for the two most important infectious diseases of the upper respiratory tract, common cold and influenza. The fact that both of these diseases leave behind them little or no resistance to future infection with their causative agents makes the problem one of particular difficulty. Little doubt exists, however, that investigators with the new knowledge at their command will devote increasing time and effort to the solution of this problem. Let us hope that at least some measure of success will attend their efforts.

year, and the age group from one to five probably has the lowest number of those who are immune

One of the most interesting facts about the disease is that sporadic cases may occur at any time, although it is well-known that in epidemic forms the highest incidence is in the late summer and fall

The treatment of all cases of infantile paralysis must be in the hands of physicians. But the public has a part to play because even suspected patients should be isolated, the room screened if possible, and all body discharges and all clothing disinfected. Rest and fresh air will be advised, but the actual securing of these will be largely in the hands of nurses and parents

It must be admitted with regret that all measures of a specific protective nature still require much more widespread study before any guarantee of absolute safety can be given. What is true of the measures designed to immunize children against the disease applies with equal force to the use of specific serums in the treatment of the disease, once it has begun. All that can be said with certainty is that convalescent serum must be used before actual paralysis has set in, if it is to be of any value

The community's responsibility during an outbreak of infantile paralysis is a heavy one. Especially is this true in the face of an epidemic. At such a time it is particularly

necessary that a search be made for all sick children, in order that they may be examined. It must provide, working with the medical profession, for such facilities as will aid in the early diagnosis, and the establishing of a central agency for the collection and distribution of serum, if the physicians so advise. Every person in the community must follow the advice of the public health officials. All of the responsible newspapers and radio chains give adequate space and time to official announcements, and these are invariably based on genuine scientific knowledge. The community must also see that all children have the proper early treatment, which is now recognized as being so important, as well as providing for the after care of all cases which have been paralyzed. So remarkable have been the medical and surgical advances in restoring paralyzed muscles to useful function, by the use of special measures, that any community which fails to provide them for its young charges is guilty of the most shameful neglect.

Some day this dreaded disease will be conquered. The medical profession is bending all its energies in an endeavor to wipe out infantile paralysis even as it has practically conquered that former scourge of childhood, diphtheria

50 E 72 St

WHAT THE PUBLIC SHOULD KNOW ABOUT THE COMMON COLD

A. R. DOCHEZ, M.D., *New York City*

Professor of Medicine, College of Physicians and Surgeons, Columbia University

The Common Cold is the most widespread and frequent infectious disease from which human beings suffer. The distribution of the disease is world-wide and it occurs at all seasons of the year, though as a rule two major outbreaks take place each year one of which reaches a peak in late October and the other in mid-January. The mid-winter outbreak is more severe in character, is accompanied by more frequent and serious complications, and causes a greater amount of lost time from school and from work. Studies in the industrial field have shown that more than fifty per cent of the time lost from work is caused by colds and their complications

Until recent years the common cold has been considered a simple disease of the respiratory tract which because of its mildness could be conveniently disregarded. A more thorough study of this disease begins to indicate that it may be the keystone of a complex series of diseases, the causative agents of which gain entrance to the human

body by way of the upper respiratory tract. The direct relationship of colds to such dangerous maladies as lobar and bronchopneumonia is well-known. Only recently, however, has it been fully appreciated that the common cold may cause severe relapses of the chronic illnesses—rheumatic heart disease, asthma, and diabetes. The frequency with which colds are accompanied by more or less prolonged infection of the nasal sinuses makes it possible that colds are among the principal contributing causes of such apparently unrelated conditions as chronic arthritis, neuritis, and various types of inflammation of the muscles. Furthermore, colds cause a predisposition to infection with the germs which give rise to such serious diseases as scarlet fever and meningitis. These few examples show how the common cold lowers resistance to many acute and chronic diseases which are among the most serious ailments which the physician is called upon to treat

The common cold is caused by an ex-

serious disease in one or two treatments! Beware the man who has no fixed residence and who moves from one city to another! Beware especially the one who claims special knowledge that no other physician possesses! All are likely to be quacks and are not to be trusted

Many a quack depends for his success on the fact that he says that all disease is produced by one cause and that all of it can be cured by reversing that cause. If medicine is to be partitioned off into a series of specialties and cults and practiced by men who have learned only one organ of the body, science is bound to fail. No part of the human body can be detached and treated as separate from the body as a whole. Concentration on an "all or nothing" policy in the treatment of disease must inevitably lead to preposterous and exaggerated claims.

Consider a typical quack of the eighteenth century. He was named James Graham. After his name he put "Servant of the Lord, O W L." The words "Servant of the Lord" indicated that he claimed divine inspiration, and the letters "O W L." stood for the words "Oh Wonderful Love." Many a cultist has wooed his followers by putting a new accent on love. James Graham promised human beings an elixir of life which would give them eternal youth and freedom from diseases. He had a temple of healing in London. Outside the temple stood a statue of Hygeia, the mythical goddess of health, and inside the temple was a statue of Venus. You could see Hygeia for nothing, but it cost two shillings to see Venus. This is what the modern ballyhoo artist calls the "come-on." It was Barnum who said that the first thing to do was to get them in, after you got them in, you could easily sell them.

Our first great American charlatan was Elisha Perkins. He claimed that all disease was due to an electrical manifestation, and he cured disease with two electrodes about the size of a nail—one of copper and the other of zinc. It cost him about twenty-five cents to manufacture each set and he sold them for \$5. The two electrodes were drawn downward over the body. Elisha warned people against drawing them upward, claiming that this would intensify disease. He promoted the sale of these devices by the use of testimonials which he obtained from those in high places, including senators, governors, Congressmen and even archbishops. In those days the leaders of society were not wont to give testimonials. The real development of the testimonial racket came with the modern methods in advertising. The testimonial still continues to be one of the chief measures in exploiting unestablished methods for the diagnosis and treatment of human ailments.

Eventually it occurred to two British doctors to make a scientific test of the methods of Elisha Perkins. They made a device similar to that of Perkins, but they used wood instead of metal. Obviously the wood could not perform as did the metal if the condition was actually electrical. They took the wooden electrodes down to the clinics where the metallic electrodes were being employed and every other patient was treated with the wooden electrodes. Just as many got well by this method as by the original method of Perkins. When this fact was made known, tractoration, or Perkinism, disappeared from the scene. That is what usually happens when the methods of the charlatan are exposed to public gaze. The Perkins ideas still persist in electrical belts, metallic rings, in heel plates of copper and zinc which, it is claimed, will ground your rheumatism while you are walking. But increasing knowledge of the fundamental facts about electricity makes people more and more doubtful of these devices.

Physicians today know that the mind plays a considerable part in our fears of illness, in the production of illness and even in its treatment. Few persons stop to realize that it is the tendency of many common diseases to recover almost in spite of what is sometimes done for them. Almost every one thinks that he knows how to cure a common cold. You can put your feet in hot water, decorate yourself with a mustard plaster, drink vast amounts of citrus drinks, take all sorts of remedies or what the government used to say is *no good* for a cold. At the end of five or six days you are usually getting well. You are likely to credit the last remedy with the cure that has occurred. The scientific man knows that it is the tendency of the cold to recover. The scientific doctor keeps you comfortable and wards off dangerous complications like pneumonia. If you happen to be treated for a cold by a quack or a quack remedy the credit for the recovery is likely to be claimed by the quack himself or the promoters of the remedy.

One of the most common diseases treated by charlatans is rheumatism. Rheumatism is one of the most frequent of disabling diseases. It is the nature of rheumatism to have periods in which the patient feels better and in which the patient feels worse. People with rheumatism can predict bad weather because they begin to feel worse before the bad weather comes and keep on feeling worse until the bad weather clears up. They usually feel fine on a nice sunny day. If they happen to be taking a "patent medicine" or if they happen to be submitting to treatment in some other manner when the improvement sets in, they are

QUACKS AND QUACKERY

MORRIS FISHBEIN, M D , Chicago, Ill

Editor Journal American Medical Association, and Hygeia, The Health Magazine

The story of quackery is a series of bizarre pictures. Whenever a new discovery is made in any field of science, some inspired charlatan is ready to adapt that discovery for his personal gain. The charlatan is known by his appearance and by the bombastic claims that he makes concerning his ability to diagnose and heal disease. His methods are in no way established as scientific or of value. Usually he acquires and holds his patents by his personality. He has a good deal of what they call "It" in Hollywood. He is likely to be a tall, commanding figure with long flowing hair. There are few bald-headed charlatans. The charlatan is likely to have after his name a long alphabetical appendage, indicating a degree of knowledge that he does not possess and that was never conferred on him by any university. Usually his titles are self-conferred or perhaps given to him by organizations which he has established for the one purpose of promoting himself and his claims.

The people who follow the charlatans are not always among the most ignorant in the community. We find them not infrequently among the well-educated. They follow the paths of charlatanism or quackery with a blind faith like that with which the fanatic follows the false religious leader. The quack, indeed, is likely to claim divine inspiration. There are few records of quacks who, once embarked on a career of charlatanism, voluntarily discontinued and went into the paths of rectitude and honesty. Actually their apostles and followers will not permit them to depart. The quack finds himself in a blind alley from which there is no escape.

Once the quack was limited in his appeals to those whom he could reach by word of mouth as he traveled about with his horse and buggy, speaking to the populace as it assembled on the city streets. Now the old medicine man of the type of Snake Oil Cooper has disappeared. The quack today is essentially a business man. He uses the modern methods of business in his promotions. Today he reaches his public by all the means which modern advertising has developed. We hear him on the radio. He lectures in great halls. He advertises in such newspapers or magazines as will carry his advertising. His circular letters reach the prospective victim in the morning mail, and his cappers insidiously solicit his victims by whispering campaigns wherever the sick and the ailing may be assembled. The quack of today reaches his hundreds of thousands

whereas the quack of a previous period reached only tens and hundreds. Today quackery is big business in every sense of the word. For that very reason it is harder to oppose and more difficult to detect and to attack.

P. T. Barnum, one of our greatest American philosophers, was the first to say that "There is a sucker born every minute." Joseph Jastrow improved on this saying by pointing out that there is a crook born every hour to take care of sixty suckers. The ratio has no doubt existed since the beginning of time and is not likely to change even with the coming of eugenic babies. Nevertheless it remained for modern times to add to this series of aphorisms concerning the quack that cynical slogan of Broadway, "Never give a sucker a break."

Remember that quackery is not confined exclusively to the medical profession. There are quacks in the law, in the ministry, in banking and in all the trades, but the quackery in the field of health is the greatest of all the menaces. Money, once lost, may sometimes be regained, but health, once lost, is regained only with the greatest of difficulty. Life, once lost, is never regained! There is no raising from the dead!

The story of quackery is a never ending tale. Theorist after theorist propounds new gospels of healing and passes at last into the great beyond which remains an unsolved problem. False practitioner after false practitioner arises and surrounds himself with fanatical followers, builds himself a sort of distinction while he lolls in the luxuries and then departs this mundane sphere, leaving it a sadder if not a wiser world. As one reads the roll of the fakirs down through the ages, one becomes almost convinced of the doctrine of transmigration of souls. The same old stories are told in the same old way with only the addition of new wrinkles based on modern discoveries. The same old green goods are wrapped up and delivered to the city and country yokelry who deposit their shekels in the drawer. The same old come-on men sit at the feet of the master dispenser of hokum to learn the technic that they too may go forth in the highways and byways and become minor prophets in their own right.

Beware the doctor who advertises! Beware the doctor who passes out handbills! Beware the doctor who has a big advertising signboard or a big electric sign in front of his office! Beware the man who guarantees a cure or who promises that he can cure any

serious disease in one or two treatments! Beware the man who has no fixed residence and who moves from one city to another! Beware especially the one who claims special knowledge that no other physician possesses! All are likely to be quacks and are not to be trusted.

Many a quack depends for his success on the fact that he says that all disease is produced by one cause and that all of it can be cured by reversing that cause. If medicine is to be partitioned off into a series of specialties and cults and practiced by men who have learned only one organ of the body, science is bound to fail. No part of the human body can be detached and treated as separate from the body as a whole. Concentration on an "all or nothing" policy in the treatment of disease must inevitably lead to preposterous and exaggerated claims.

Consider a typical quack of the eighteenth century. He was named James Graham. After his name he put "Servant of the Lord, O W L." The words "Servant of the Lord" indicated that he claimed divine inspiration, and the letters "O W L." stood for the words "Oh Wonderful Love." Many a cultist has wooed his followers by putting a new accent on love. James Graham promised human beings an elixir of life which would give them eternal youth and freedom from diseases. He had a temple of healing in London. Outside the temple stood a statue of Hygeia, the mythical goddess of health, and inside the temple was a statue of Venus. You could see Hygeia for nothing, but it cost two shillings to see Venus. This is what the modern ballyhoo artist calls the "come-on." It was Barnum who said that the first thing to do was to get them in, after you got them in you could easily sell them.

Our first great American charlatan was Elisha Perkins. He claimed that all disease was due to an electrical manifestation, and he cured disease with two electrodes about the size of a nail—one of copper and the other of zinc. It cost him about twenty-five cents to manufacture each set and he sold them for \$5. The two electrodes were drawn downward over the body. Elisha warned people against drawing them upward, claiming that this would intensify disease. He promoted the sale of these devices by the use of testimonials which he obtained from those in high places, including senators, governors, Congressmen and even archbishops. In those days the leaders of society were not wont to give testimonials. The real development of the testimonial racket came with the modern methods in advertising. The testimonial still continues to be one of the chief measures in exploiting unestablished methods for the diagnosis and treatment of human ailments.

Eventually it occurred to two British doctors to make a scientific test of the methods of Elisha Perkins. They made a device similar to that of Perkins, but they used wood instead of metal. Obviously the wood could not perform as did the metal if the condition was actually electrical. They took the wooden electrodes down to the clinics where the metallic electrodes were being employed and every other patient was treated with the wooden electrodes. Just as many got well by this method as by the original method of Perkins. When this fact was made known, tractors, or Perkinism, disappeared from the scene. That is what usually happens when the methods of the charlatan are exposed to public gaze. The Perkins ideas still persist in electrical belts, metallic rings, in heel plates of copper and zinc which, it is claimed, will ground your rheumatism while you are walking. But increasing knowledge of the fundamental facts about electricity makes people more and more doubtful of these devices.

Physicians today know that the mind plays a considerable part in our fears of illness, in the production of illness and even in its treatment. Few persons stop to realize that it is the tendency of many common diseases to recover almost in spite of what is sometimes done for them. Almost every one thinks that he knows how to cure a common cold. You can put your feet in hot water, decorate yourself with a mustard plaster, drink vast amounts of citrus drinks, take all sorts of remedies or what the government used to say is no good for a cold. At the end of five or six days you are usually getting well. You are likely to credit the last remedy with the cure that has occurred. The scientific man knows that it is the tendency of the cold to recover. The scientific doctor keeps you comfortable and wards off dangerous complications like pneumonia. If you happen to be treated for a cold by a quack or a quack remedy the credit for the recovery is likely to be claimed by the quack himself or the promoters of the remedy.

One of the most common diseases treated by charlatans is rheumatism. Rheumatism is one of the most frequent of disabling diseases. It is the nature of rheumatism to have periods in which the patient feels better and in which the patient feels worse. People with rheumatism can predict bad weather because they begin to feel worse before the bad weather comes and keep on feeling worse until the bad weather clears up. They usually feel fine on a nice sunny day. QUACKS AND QUACKERY

MORRIS FISHBEIN, M D, *Chicago, Ill*

Editor Journal American Medical Association, and Hygeia, The Health Magazine

The story of quackery is a series of bizarre pictures. Whenever a new discovery is made in any field of science, some inspired charlatan is ready to adapt that discovery for his personal gain. The charlatan is known by his appearance and by the bombastic claims that he makes concerning his ability to diagnose and heal disease. His methods are in no way established as scientific or of value. Usually he acquires and holds his patents by his personality. He has a good deal of what they call "It" in Hollywood. He is likely to be a tall, commanding figure with long flowing hair. There are few bald-headed charlatans. The charlatan is likely to have after his name a long alphabetical appendage, indicating a degree of knowledge that he does not possess and that was never conferred on him by any university. Usually his titles are self-conferred or perhaps given to him by organizations which he has established for the one purpose of promoting himself and his claims.

The people who follow the charlatans are not always among the most ignorant in the community. We find them not infrequently among the well-educated. They follow the paths of charlatanism or quackery with a blind faith like that with which the fanatic follows the false religious leader. The quack, indeed, is likely to claim divine inspiration. There are few records of quacks who, once embarked on a career of charlatanism, voluntarily discontinued and went into the paths of rectitude and honesty. Actually their apostles and followers will not permit them to depart. The quack finds himself in a blind alley from which there is no escape.

Once the quack was limited in his appeals to those whom he could reach by word of mouth as he traveled about with his horse and buggy, speaking to the populace as it assembled on the city streets. Now the old medicine man of the type of Snake Oil Cooper has disappeared. The quack today is essentially a business man. He uses the modern methods of business in his promotions. Today he reaches his public by all the means which modern advertising has developed. We hear him on the radio. He lectures in great halls. He advertises in such newspapers or magazines as will carry his advertising. His circular letters reach the prospective victim in the morning mail, and his cappers insidiously solicit his victims by whispering campaigns wherever the sick and the ailing may be assembled. The quack of today reaches his hundreds of thousands

whereas the quack of a previous period reached only tens and hundreds. Today quackery is big business in every sense of the word. For that very reason it is harder to oppose and more difficult to detect and to attack.

P. T. Barnum, one of our greatest American philosophers, was the first to say that "There is a sucker born every minute." Joseph Jastrow improved on this saying by pointing out that there is a crook born every hour to take care of sixty suckers. The ratio has no doubt existed since the beginning of time and is not likely to change even with the coming of eugenic babies. Nevertheless it remained for modern times to add to this series of aphorisms concerning the quack that cynical slogan of Broadway, "Never give a sucker a break."

Remember that quackery is not confined exclusively to the medical profession. There are quacks in the law, in the ministry, in banking and in all the trades, but the quackery in the field of health is the greatest of all the menaces. Money, once lost, may sometimes be regained, but health, once lost, is regained only with the greatest of difficulty. Life, once lost, is never regained! There is no raising from the dead!

The story of quackery is a never ending tale. Theorist after theorist propounds new gospels of healing and passes at last into the great beyond which remains an unsolved problem. False practitioner after false practitioner arises and surrounds himself with fanatical followers, builds himself a sort of distinction while he lolls in the luxuries and then departs this mundane sphere, leaving it a sadder if not a wiser world. As one reads the roll of the fakirs down through the ages, one becomes almost convinced of the doctrine of transmigration of souls. The same old stories are told in the same old way with only the addition of new wrinkles based on modern discoveries. The same old green goods are wrapped up and delivered to the city and country yokels who deposit their shekels in the drawer. The same old come-on men sit at the feet of the master dispenser of hokum to learn the technic that they too may go forth in the highways and byways and become minor prophets in their own right.

Beware the doctor who advertises! Beware the doctor who passes out handbills! Beware the doctor who has a big advertising signboard or a big electric sign in front of his office! Beware the man who guarantees a cure or who promises that he can cure any

acids and those who oppose alkalis Vegetarians attach undue evils to the eating of meat, and whole-wheat fanatics say that white bread causes cancer There is not the slightest scientific evidence to support the view that the eating of wholesome quantities of any single item of diet, such as meat, bread or any other of the fundamental foods, is dangerous

Then, too, the last twenty years have seen the rise of the plastic surgeon and beauty quack. Cosmetic operations are most commonly sought by elderly women in love with young men, by aging actresses who still wish to play ingenues, by women whose husbands have lost interest in them, by pugilists who have fought to financial success at the cost of facial continuity, and finally by foolish salesgirls, clerks, aspirants to the movies, and unemployed sheiks There is, of course, a legitimate field for the surgery of the repair of deformities, but the legitimate surgeon does not advertise, he has no "come-ons" and he does his operating in reputable hospitals

Of all the charlatans who have preyed on mankind since the earliest times, the most despicable are the ghouls who feed on the bodies of those who are dead or dying from cancer The medical profession today does not know the cause of cancer It does know that the one real hope for any patient with this condition is early diagnosis and prompt treatment either by surgery or by the use of radium and the x-rays We can point now to innumerable cases of people with cancer who have been given almost a normal life expectancy, after the diagnosis of can-

cer was made, through the benefits derived from these methods of treatment Yet throughout our country and Canada today there are charlatans who exploit serums, vaccines, caustic pastes, and mixtures of herbs and roots and vegetables which are alleged to be of specific virtue in the treatment of cancer but which have been shown by the passage of time and by scientifically controlled experimentation to be completely without merit Knowing the fear that pervades the population in relation to cancer and knowing that the people who are dying of this disease will grasp at any straw of hope which may be offered, these charlatans take even from the poor the last few pennies that have been laid aside for purposes of burial, leading them on by unwarranted promises of success

When the famous Pasteur was asked by his students for some advice to guide them in their scientific careers, he said to them, "Be skeptical" A certain amount of skepticism is your only salvation against the wiles of the quack and the charlatan Be skeptical, and when you are in doubt, ask your family doctor whose reply will be based on a knowledge of medicine and who will answer you with a statement in which you may have confidence The Bureau of Investigation of the American Medical Association has a card index listing hundreds of thousands of quacks and quackeries, of nostrums and fraudulent medicines If you are in doubt, write to the American Medical Association at Chicago The information is freely available to any one as a service of the doctors of this country for the health of the people

SLEEP

FOSTER KENNEDY, M D, *New York City*

It is truly strange that we know almost nothing of the mechanism by which sleep is produced We spend almost a third of our lives asleep and the physiology of this condition is less understood than is that of the digestion or respiration Further, the fact that we know little or nothing of the background of this state of being doesn't seem to occur even to the minds of persons who spend their lives in physiological research The technical literature is small and speculative rather than experimental We have learned however, only in the past twenty years that there is one area in the brain—a part of the hypothalamus—which if stricken with disease causes the individual to sleep usually too much, possibly twenty-two or three hours a day, in fact passes into a state of hibernation, however there may come from such an illness other varie-

ties of interference with sleep A reversal of the ordinary sleep rhythm may occur so that with dawn drowsiness supervenes, and towards evening, wakefulness takes place In such persons if the organic needs are denied—should the person persist in trying to work through the day, they do so groggy and vacillating in action and power of decision Further, I have seen disease of this small brain area do away for nine days and nights with any power or desire for sleep and in this period the man was able to work and to feel well One would like to know how to reproduce this situation artificially, it is unlikely that we shall ever make an efficient life span of more than a century, the cellular complexity of our bodies imposes mortality upon us, but I sincerely believe that a method of sleep substitution is not beyond the wit of man

likely to give credit for the improvement to the last treatment. On this natural tendency of disease the charlatan bases his claims and the promotion of his methods. Nowadays people with rheumatism scurry hither and thither from state to state, from nation to nation, trying to find some magic route to cure and giving each new treatment credit for benefit which would have occurred just the same had they remained at home. But there might not have been the same psychologic effect with the common methods of treatment employed by the family doctor.

Let us distinguish between charlatanism and quackery on the one hand and adulteration and fraud on the other. When the grocer puts sand in the sugar, when you buy wool stockings that are one-half cotton, and when the motor car that the salesman told you would run 30,000 miles has fallen apart at twenty, the dealers are not practicing quackery, they are practicing misbranding, fraud, and adulteration. But when a doctor says that he can cure all forms of rheumatic disease by twisting the feet, and when under the guise of such treatment he twists the feet for patients who are suffering from the results of meningitis and infantile paralysis, patients who are staggering to their doom with multiple sclerosis, myasthenia gravis and the shaking palsy, he is practicing a cruel and deceptive form of quackery. He knows and the medical profession knows that there is no hope in such treatment for alleviation or benefit of the conditions concerned. And those who spend their money in traveling to the shrines of quackery to receive these treatments are in most instances bestowing on the quack the money that they should save for proper nursing and reasonable care during their years of invalidism. This is quackery in its most serious form.

More amusing perhaps is that form of charlatanism which promises youth and vim, vigor and vitality to sexagenarians with accent on the "sex." Here enters exploitation of our new knowledge and our great ignorance of the glands. It is to the eternal credit of the Federal Radio Commission and the Federal Communications Division that they have barred from the air waves in the United States two charlatans who now befoul the American atmosphere with nightly communications from across the Rio Grande. I refer, of course, to those stations which regularly solicit American patronage for operations on the glands and for the use of unestablished cures for cancer. The mere fact that these charlatans can no longer broadcast their messages from American radio stations should indicate to any American listener the utterly unestablished character of their claims and the danger that is

inherent in such practices. Yet repeated representations made to the government of Mexico have failed to bring about a cessation of the blatant and monotonous reverberations that lead the senile and the suffering into the hands of these quacks. Neither goat glands nor any other glands will rejuvenate the aged. Yet the graybeards still go tottering with hands outstretched, seeking the mythical fountain of youth that Ponce de Leon sought in vain.

One of the latest developments in quackery is the psychoanalytic or psychologic quack. Out of the interests in these fields during the last twenty-five years has come a new species of pedler of psychologic treatment known as the practical psychologist and the character analyst. Their doctrines are platitudes which strike the intellect of Homo Americanus with the force of direct communications from high Olympus. Their appeal is to the fundamental desires and weaknesses of this same Boobus Americanus: his love for financial success, social prominence, and his desire for relief from vague and fancied ills. Their chief source of income is from women. In private conferences and for a few pitiful dollars, these psychologic quacks, completely uninformed concerning true psychology, attempt to advise women concerning their worries and their mental problems. Women suffering from ennui or idleness, their faces elaborated with artifices to simulate the long lost buoyancy of youth, sigh happily at the dreams and mirages that these charlatans prepare for them. They promise health and happiness, and they give a little erotic stimulation by commercializing psychology.

The credulity of mankind in regard to new apparatus is astounding. All sorts of rays, electric shocks, and vibrators are being sold to people as "cure-alls" when their uses in disease are exceedingly limited. The success of ultra-violet in the control of rickets is no indication that it will grow hair on a hereditarily bald head or make beautiful a skin that is full of pimples. Thousands of people have tried to shake their bodies into health with vibrating belts and have instead shaken loose organs that were doing pretty well anchored where nature anchored them.

The most persistent of recent quacks are food faddists. Foods are sold as health foods, as tonic foods and as vitalizing foods. We are warned against dangerous combinations, and the vitamins are promoted as producers of longevity. The wise man of today eats a widely varied diet and in that diet need fear no deficiencies. We are admonished at every turn to eat more of this or that or to confine ourselves wholly to some particular diet. We have those opposed to

acids and those who oppose alkalis Vegetarians attach undue evils to the eating of meat, and whole-wheat fanatics say that white bread causes cancer There is not the slightest scientific evidence to support the view that the eating of wholesome quantities of any single item of diet, such as meat, bread or any other of the fundamental foods, is dangerous

Then, too, the last twenty years have seen the rise of the plastic surgeon and beauty quack. Cosmetic operations are most commonly sought by elderly women in love with young men, by aging actresses who still wish to play ingenues, by women whose husbands have lost interest in them, by pugilists who have fought to financial success at the cost of facial continuity, and finally by foolish salesgirls, clerks, aspirants to the movies, and unemployed sheiks There is, of course, a legitimate field for the surgery of the repair of deformities, but the legitimate surgeon does not advertise, he has no "come-ons" and he does his operating in reputable hospitals

Of all the charlatans who have preyed on mankind since the earliest times, the most despicable are the ghouls who feed on the bodies of those who are dead or dying from cancer The medical profession today does not know the cause of cancer It does know that the one real hope for any patient with this condition is early diagnosis and prompt treatment either by surgery or by the use of radium and the x-rays We can point now to innumerable cases of people with cancer who have been given almost a normal life expectancy, after the diagnosis of can-

cer was made, through the benefits derived from these methods of treatment. SLEEP

FOSTER KENNEDY, M D, *New York City*

It is truly strange that we know almost nothing of the mechanism by which sleep is produced. We spend almost a third of our lives asleep and the physiology of this condition is less understood than is that of the digestion or respiration Further, the fact that we know little or nothing of the background of this state of being doesn't seem to occur even to the minds of persons who spend their lives in physiological research The technical literature is small and speculative rather than experimental We have learned however, only in the past twenty years that there is one area in the brain—a part of the hypothalamus—which if stricken with disease causes the individual to sleep usually too much, possibly twenty-two or three hours a day, in fact passes into a state of hibernation, however there may come from such an illness other varie-

ties of interference with sleep A reversal of the ordinary sleep rhythm may occur so that with dawn drowsiness supervenes, and towards evening, wakefulness takes place In such persons if the organic needs are denied—should the person persist in trying to work through the day, they do so groggy and vacillating in action and power of decision Further, I have seen disease of this small brain area do away for nine days and nights with any power or desire for sleep and in this period the man was able to work and to feel well One would like to know how to reproduce this situation artificially, it is unlikely that we shall ever make an efficient life span of more than a century, the cellular complexity of our bodies imposes mortality upon us, but I sincerely believe that a method of sleep substitution is not beyond the wit of man

to encompass. After all Thomas Moore told us that the best of all ways to lengthen our days is to take a few hours from the night! It is but an interruption of our happy consciousness. The sense of wonder is the yardstick, the measurement of our aging, if it be alive we are young, and if it be not, we die though we be but twenty years a-growing. So we live by as much as we feel, as we think, as we act,—and sleep kills or almost kills all these. So perhaps it is an unconscious wisdom which makes us ignore the mechanism of our sleeping, a wishful thinking, which will be displaced and give rise to a knowledge of the secret of wakefulness and conscious living.

Further, the centers in the midbrain which have to do with this vital periodicity in our living are intimately connected with important centers of metabolism for control of interchange of tissue and necessary chemicals. The frequent association of abnormal lethargy with obesity is evidence of a close relationship between pathological sleep and metabolic abnormality.

The French—shrewd and thrifty folk—say "qui dort dine"—he who sleeps, eats, and undoubtedly the wastage of material is less in our sleeping than in our waking activities. Further, the temperature falls in sleep, but should the external temperature fall to a point threatening a hibernating animal, that animal awakens.

We have heard often the old phrase that beauty sleep is the sleep before midnight. I do not know quite the meaning of this aphorism but it would seem that physiological knowledge can support its idea. We do not just sleep when we are fatigued, we sleep to prevent fatigue. If we only sleep when exhausted, we have to repair a brain cell that has been temporarily more greatly damaged. Yes, fatigue makes the look of the cells in our brains different, they grow shapeless, swollen, and dim in pattern when thoroughly tired. Therefore if we put them in the hands of Nature's sweet nurse early enough, before extreme changes have occurred, we get better and quicker repair—a sleep that brings health and beauty to other tissues.

All the same, we run the risk these days of doing what Christ told us not to do—of taking too much thought for the morrow—of being over solicitous of ourselves in hygienic affairs. It is certain that many people get panicky in an absurd manner if sleep fails them somewhat. They think their reason will topple unless they're allowed to lie unconscious as Crocodiles for a full third of each twenty-four hours. I would assure and reassure such anxious ones that Nature will impose on them what sleep they need—and that Morpheus will gather them in be-

fore any extremity be reached. Many elderly people complain of early wakefulness—they waken at four in the morning—they may even complain at six—they would sleep socially, not on their own terms but in terms of those who serve them. They don't know what to do with the hours that must pass before others are up and about. This is surely unwise behavior—a child must sleep much, a man much less, and an old man very little. The old burn less than they did in younger days, so they have less wastage to repair, let them not sleep in the terms of their younger selves but in terms of their own serenity. Their lesser need of sleep adds to their living time which runs short. They should get up, drink a thermos of coffee, throw a match at the fire, start writing letters or reading undisturbed by an importunate and over busy world—only then in those early hours are they the Masters of their Fates and the Captains of their Souls.

During the retreat of the Fifth British Army in March 1918, some of the soldiers were so exhausted that sleep fell on them like a coma. I used to look in them for the position of the eyeballs in sleep—for they would not waken when I raised their eyelids with my fingers. I began to practice putting my eyes, by will, in this position of sleepfulness and found that a few seconds later I felt sleepy and yawned—an automatic associated reflex over which I had no voluntary control. Ever since, I have found this trick a useful one with which to woo slumber, especially when combined with voluntary relaxation of muscles in the limbs, neck, jaw, and tongue—these last almost always forgotten,—don't eat solids for two or three hours before sleep time—some stewed fruit, hot toddy, a glass of ale, or better still hot milk are all helpful. The other requisite for sleep is a refusal to think in bed. Having relaxed all your muscles, try to imagine yourself looking down a long hollow barrel—like the shooting gallery of a country fair—which is ended far away by a white target disk lighted from behind. If you succeed for a very short period in preventing images or ideas from crossing that disk you will find yourself quickly self-hypnotized and drop into unconsciousness—an occasional failure in this technic need cause no discouragement. For again I would remind you that while at present we need this little death in life, it's not really all it's said to be—much of it is really a terrible waste of time. I hope we may find some good way out of part of it at least, and finally I would congratulate those who are lucky enough now to be able to live healthy, longer, by sleeping less.

WHY ORGANIZED MEDICINE

IAGO GALDSTON, M D, *New York City*

Executive Secretary, Medical Information Bureau, New York Academy of Medicine

Like woman's work the doctor's work is never done. But whereas woman's work sooner or later becomes fairly routinized, that of the doctor never congeals into a fixed pattern. If it does then he is quickly outmoded—he falls behind the times. For of all the so-called learned professions, that of medicine is most mercurial. "Law," Osler said, "constantly looking back, has its forms and procedures, its precedents and practices. Once grasped the certainties of divinity make its study a delight and its practice a pastime, but who can tell of the uncertainties of medicine as an art?" Hardly a year passes but some advance is made in our science, an advance which not only adds to the knowledge body of medicine, but which frequently necessitates the revision of fundamental concepts, the unlearning of what was originally acquired at the cost of much labor.

Consider for example the revolution created by the discovery of insulin, and more recently by the introduction of liver treatment for pernicious anemia. The repercussions from these literally explosive discoveries have not yet spent themselves. For apart from the fact that we now have two new means for the treatment of heretofore practically incurable and fatal diseases, we also have a large body of new facts concerning the underlying disease mechanisms, facts which are refashioning our theoretical and practical concepts of nutrition and metabolism. And what need we say concerning the discovery of vitamins, or of fever therapy, or the discovery of the female sexual hormone, of the advances made in the study on the relationship of emotional disturbances to the so-called functional diseases. The public press and the radio daily carry notices of the progress made in these fields. What is not so patent nor so public is how these advances are attained, and their effects on the actual practice of medicine. Behind the scenes there is operative what we vaguely term organized medicine, an instrumentality which ties together, which guides, educates, and regulates the practitioners of medicine. I wish it were possible for you to see at first sight how organized medicine functions. Start for example with your local so-called county medical society. Practically every county in the United States has its medical society. Every medical graduate who is ethical in his practice is eligible for membership, nay more, he will be urged to belong and it's a poor or

odd man who chooses to stay outside the fold. And what does the county society do? Well, probably its first activity is to maintain a library. No doctor could possibly own and house all the periodicals, books, reports, etc., for which he had need. In the county society's library the profession's resources are pooled and are thus made available to every medical man. In many communities the library is open not only to members, but to non-member physicians, internes, nurses, public health workers, and to the general public.

Next to the library come the regular and special medical meetings. Here doctors foregather to compare notes, to discuss disease causation, diagnoses, treatment, and disease prevention. Sometimes some well-known authority is invited to address the county membership on his specialty, in other words, to give to his fellow practitioners the benefits, the fruits of his years of devoted study, experimentation, and experience. At other times some local Hippocrates will stand up to lecture his contemporaries on some matter concerning which he believes he has a message to deliver. Here he runs the gauntlet of his best friends and severest critics. And eager as men are to be on the program, so eager are the rest to take a pot shot at them. At these meetings the crude ore of theory and experience are fired in the crucible of critical review and discussion—and I can assure you from personal experience that the heat of debate is such that what is not gold is soon reduced to ashes, which are not infrequently poured with scorn upon the head of the speaker.

But do not gather from this that county meetings are a sort of Roman holiday, like the initiation ordeals at the lodge. These inquisitorial discussions are a safeguard for the profession and the public. For in medicine no discovery is valid until it has been confirmed by numerous investigators repeating the work of the claimant. The greatest of medical men have been wrong in some things medical. The great Robert Koch, he who discovered the germ of tuberculosis and that of cholera, also believed he discovered a cure for tuberculosis. It took five years and the independent study of many men in many parts of the world to show that tuberculin was not a cure for tuberculosis. How many of our very best research men and clinicians have had the mistaken idea that they had discovered the

cause or the cure of cancer. Some day, and at that possibly soon, some one or more likely a group of men will solve the riddle of cancer. But you may be certain, before that most eagerly hoped-for news is given the world, its authenticity will have been checked, double checked, and more. We have been wrong so many times before.

But back to our county society. Some meetings will be devoted to public health. If the community's milk is poor, if its waters are polluted, if the insect pest is too troublesome, or ragweed too rampant, if too many cases of diphtheria are found to occur, or the school children's teeth are bad, or the maternal mortality is high, you may be certain some one will speak up. A meeting will be held, a committee will be appointed, and sooner or later, something will be done. Let me not seem to claim greater social consciousness for medical men than is found in other professions. It's rather a matter of meter—the doctor daily deals with man and his environment. If he is more commonly concerned than say the lawyer or the minister is with noise abatement, the smoke nuisance, adulterated foods and the like, it is because in his daily round he is forced to take notice of them, even as the tailor sees the missing buttons and the shoemaker the run-down heels.

Finally, and that only because time is limited, we come to the matter of ethics. Organized medicine is governed by and governs through a code of ethics self-imposed, self-administered. No professional man has more privileges accorded him than the doctor. From the caduceus on his car, which allows him parking privileges beyond the common run, to his professional secrecy which may be invaded only by order of the court, the doctor is endowed with prerogatives denied the others. This is no gratuitous honor conferred on the doctor. The privileges come as the obverse of his responsibilities. But whatever their source, the doctor does have uncommon privileges, and these must be safeguarded by professional supervision, lest they be exploited.

Since the most ancient of times medical men have been governed by a code of ethics. The precepts differed accordingly as the code was Egyptian, Greek, early Christian or medieval, but through all there ran the guiding moral conception of the duties and obligations of the physician. The Oath of Hippocrates, framed in days when Greek medicine was in its glory, is the pledge of

the medical man today, given as he is invested with the dignity of his calling.

"I swear by Apollo the Physician," so runs the Oath, "and Aesculapius and Hygeia, and Panacea, and all the gods and all the goddesses—and I make them my judges—that this mine oath and this my written engagement I will fulfill so far as power and discernment shall be mine.

"So far as power and discernment shall be mine, I will carry out regimen for the benefit of the sick, and will keep them from harm and wrong. To none will I give a deadly drug, even if solicited, nor offer counsel to such an end, likewise to no woman will I give a destructive suppository, but guiltless and hallowed will I keep my life and mine art.

"Into whatsoever houses I shall enter I will go for the benefit of the sick, holding aloof from all voluntary wrong and corruption, including venereal acts upon the bodies of females and males whether free or slaves. Whatsoever in my practice or not in my practice I shall see or hear, amid the lives of men, which ought not to be noised abroad—as to this I will keep silence, holding such things unfitting to be spoken.

"And now if I shall fulfill this oath and break it not, may the fruits of life and of art be mine, may I be honored of all men for all time, the opposite, if I shall transgress and be forsworn."

To this ancient pledge have been added such ethical precepts as the exigencies of modern times require, but the spirit remains the same. And this spirit is embodied, nurtured, and preserved by that fraternity of practitioners whom we have learned to collectively call organized medicine. The doctor has been lampooned by the clown and the wit. He has been eulogized by the best of men. But it is a fact that dealing as he does with life and death, practicing an art wherein, as Hippocrates observed, "Experience is fallacious and judgment difficult," he needs the sustaining fellowship of his confreres, to teach and to learn, to compare notes and to match experiences, to hold common counsel on what concerns the profession and what affects mankind, and mostly so that the great honor and the great responsibilities of the physician be never lost sight of. For it is true, as it was said in ancient times that "Men in no way approach so nearly to the gods as in giving health to men."

District Branch Meetings

Scientific Program of the thirtieth annual meeting of the Sixth District Branch of the Medical Society of the State of New York will be held at Willard Straight Hall, Cornell University, Ithaca, Thursday, September 17

MORNING SESSION

10 00 A M Eastern Standard Time

Discussion of New York State Syphilis Program, William A Brumfield, Jr, M D, State Department of Health, Albany Discussion opened by V A Van Volkenburgh, M D, Ithaca.

"Diagnosis and Treatment of Anal Abscess and Fistula," John C M Brust, M D, Syracuse

Colored Movies of Heat Treatment of Gonorrheal Infections, Stafford L Warren, M D and Charles M Carpenter, M D, Rochester Discussion opened by Stewart

S Piper, M D, Elmira
Luncheon

AFTERNOON SESSION

Addresses by Floyd S Winslow, M D, President of the Medical Society of the State of New York, David J Kaliski, M D, Chairman of the Workmen's Compensation Bureau, Peter Irving, M D, Secretary of the Medical Society of the State of New York

Biggs Memorial Hospital—A Model Demonstration of Physical Plant and a Discussion of the Policy of the Hospital, John K. Deegan M D, Physician in charge, Albany

Diseases of the Lungs Chevalier Jackson, M D, and Chevalier L Jackson, M D Philadelphia, Pa. Discussion opened by Ethan F Butler, M D, Ithaca

Entertainment will be provided for the ladies

The scientific program of the thirtieth annual meeting of the Seventh District Branch of the Medical Society of the State of New York to be held on Thursday, September 24, at the Willard State Hospital, Willard, is as follows

MORNING SESSION

10 00 A M Eastern Standard Time

Floyd S Winslow, M D, President, Medical Society of the State of New York, "Progress of the Society"

David J Kaliski, M D, Director Workmen's Compensation Bureau, Medical Society of the State of New York, "Problems and Progress of the Bureau"

Frederic E. Elliott, M D, Chairman Committee on Economics, Medical Society of the State of New York, "Current Medical Economics"

Peter Irving, M D, Secretary, Medical Society of the State of New York, "The State Society Office"

(The presentations of Doctors Winslow, Kaliski Elliott, and Irving will be open for general discussion)

Arthur Krida, M D, Chief Orthopedic Surgeon, Bellevue Hospital, New York City, "Surgery of the Knee Joint" Discussion will be opened by Edward T Wentworth, M D, Rochester

Harry Worthing, M D, Superintendent, Willard State Hospital, Willard, N Y, "Announcements"

1 00 P M—Luncheon (75 cents)

AFTERNOON SESSION

2 00 P M

Ross E Herold, M D, Clinical Director of Psychiatry Willard State Hospital, "Dry Clinic."

Edward G Winkler, M D, Buffalo, "Miscellaneous Procedures in Gynecology"—a presentation of various office procedures and the technic of the "Watkins Interposition Operation" (moving pictures—one hour) Discussion will be opened by A James Bennett, M D, Auburn

W J Merle Scott, M D, Rochester, "The Differentiation of Benign and Malignant Lesions in the Gastrointestinal Tract." Discussion will be opened by Phillip W Skinner, M D, Geneva

POSTPONEMENT NOTICE

The first international conference on fever therapy, originally scheduled for the end of September, 1936, has been postponed because of numerous requests, to permit more time for the preparation of material The new dates set for this Conference are March

30 to April 2, 1937 The sessions will be held at the College of Physicians and Surgeons, Columbia University

Further information may be obtained from the General Secretary, Dr William Bierman, 471 Park Avenue, New York City

cause or the cure of cancer. Some day, and at that possibly soon, some one or more likely a group of men will solve the riddle of cancer. But you may be certain, before that most eagerly hoped-for news is given the world, its authenticity will have been checked, double checked, and more. We have been wrong so many times before.

Medical News

Secretaries of County and local Medical Societies are requested to send the programs of coming meetings to this department one month in advance, for the information of members who may be interested

Kings County

NEW YORK STATE does not protect cancer sufferers from treatment by "irregular" physicians, the "heartless parasites" of the medical profession

This charge is made by Dr John E Jennings, director of the new Brooklyn Cancer Institute

"The State so far is unable to guard its people against the incompetent practice of medicine," Dr Jennings told a Brooklyn *Eagle* reporter who interviewed him in his offices at 23 S Portland Ave

"The machinery is set up to deal with quacks who treat cancer with promises and salves but no serious consideration has been given to prevent them from practicing their trade. The medical profession as a whole cannot deal with them, since it is not asked to prescribe for the State or the community, but for individuals only"

Dr Jennings was enthusiastic over the possibilities of the new cancer institute in fighting the disease

The children's building at the Kings County Hospital is being remodelled with WCA and city funds for the sole use of the Cancer Institute, he revealed The unit will accommodate eighty to one hundred cases It will be outfitted with the latest equipment not only for x-ray, surgical, and radium treatment, but also for research Dr Jennings will head a staff of fifty

"As a rough estimate, 3,000 cases are certified to the Health Department each year as dying of cancer in Brooklyn," Dr Jennings said "Conservatively speaking, two-thirds of these are indigent Our small hospital will have no relation to the amount as a whole, but we hope to care for many through Commissioner Goldwater's expansion of our social service work"

TWO DOCTORS AND TWO GRADUATE NURSES were held on Aug 18 on charges of performing illegal operations while Brooklyn authorities investigated the "biggest ring of abortionists" in that borough and charged an illegal hospital was operated at 4746 Ocean Ave

Records of the institution were seized They contained the names of hundreds of patients The prices charged for the operations ranged from \$75 to \$300 From January 1 to August 1, according to the records, the institution had \$5,618 worth of business

DR THOMAS MORTIMER LLOYD, eighty-two, who formerly for forty years practiced medicine in Brooklyn, died on Aug 21 of heart trouble in his Summer home on Academy Lane, Bellport, L I Prior to his retirement from active practice ten years ago, Dr Lloyd had been associated with many Brooklyn hospitals

Monroe County

THE WILL OF Dr Ira T Johnson, of Rochester, who died on Aug 4, at the age of seventy-three, wipes out all unpaid bills of his patients for professional services The unusual paragraph in the testament reads

"I direct my executors to cancel and discharge as fully paid any and all accounts due me for medical or surgical treatment rendered by me to any and all of my patients"

His estate is estimated at \$175,000

Nassau County

THE SEPTEMBER MEETING of the Medical Society of the County of Nassau will be held on the 29th at the Nassau County Bar Association Club House at Mineola

THE *Nassau Medical News*, organ of the County Medical Society, suggests in an editorial on "Sickness Taxation"

Decidedly we want no sickness taxation even if it is disguised under the more euphemistic title of Health Insurance Election is just ahead of us, the medical profession might with considerable profit inquire of the various candidates for office just what is their attitude toward this threat against the pocketbook as well as health of our workers

New York County

APPEARING BEFORE BUDGET DIRECTOR Rufus E McGahen, Health Commr John L Rice on Aug 13 requested a departmental allotment of \$5,867,664 for next year, an increase of \$1,483,273 over the 1936 appropriation

This sum must be granted if both the present program and new projects contemplated by the Health Department are to be conducted with the required efficiency, the commissioner explained He considered the increase an investment rather than an expense

"The budget of the Health Department might readily be doubled to give full service,

and the results in such medical service would be an investment rather than an expense," Dr Rice said.

Heading the list of new health agencies planned by the department is a pneumonia service for which Dr Rice requests an appropriation of \$100,000.

This service, it was said, would make possible the distribution of serums to hospitals and physicians combating pneumonia.

Dr Rice claims proper distribution of this serum would greatly curtail the city death rate. Pneumonia causes approximately 6,000 deaths in New York City every year.

The sum of \$35,700 was asked to finance a detailed survey of tuberculosis conditions particularly in Harlem where the disease is most prevalent. X-rays of those believed to be tubercular would constitute a basic feature of the survey.

The commissioner revealed plans for the construction of four new health centers in 1937. These, he explained, are part of a ten-year program which by 1945 is expected to give thirty such centers to the city.

He explained the need for the establishment of additional clinics and the expansion of existing clinics devoted to the diagnosis and prevention of tuberculosis and social diseases.

A total of \$20,600 is requested for the equipment of twelve new baby health stations, seven new dental clinics, and five new eye clinics.

DR CHARLES A. ELSBERG, chief of the surgical service of the Neurological Institute was honored on his sixty-fifth birthday on Aug. 24 at a tea given by his colleagues of the medical staff at the institute.

Hostesses of the occasion were Mrs. H. P. Davison, vice-president of the board of trustees and Mrs. Courtlandt Nicoll, a member of the board. Guests included members of the board, doctors, nurses, and officials of the institute and many noted surgeons and physicians.

Dr. Leo M. Davidoff presented Dr. Elsberg with a volume of the Bulletin of the Neurological Institute, called "The Elsberg Anniversary Volume," which includes forty original articles by Dr. Elsberg and his associates.

Other speakers were Dr. J. Bentley Squier, Dr. Frederick Tilney, Dr. Cassius Watson and Dr. Dudley Roberts.

Niagara County

THE ANNUAL OUTING of the Niagara County Medical Society was held on Aug. 19 at Lookout Point Golf and Country Club, Fonthill, Ont. Dinner was served, basketball, quoits, and other sports were scheduled. About eighty members were in attendance.

DR C. W. GEORGE, Secretary of the Medical Society of the County of Niagara, reports that the September meeting was held on the 8th at the Lox Plaza Hotel at Lockport. Dr. James K. Quigley, of the University of Rochester Medical School, read a paper on Cesarean Section.

Oneida County

REVISION OF THE CONSTITUTION of the Utica Academy of Medicine will be considered at the October meeting.

THE ROME HOSPITAL medical staff, in a report signed by Drs. William B. Reid, John E. Groff, and Dan Mellen, on request of the board of trustees of the hospital, on Aug. 20 recommended to Mayor Ray Armstrong the construction of a new one hundred-bed hospital as a Public Works Administration project.

The report recommends

That the City of Rome construct a new 100-bed hospital.

That a grant of \$135,000 be requested from the Federal government.

That a loan of \$165,000 be requested from the same source with permission to sell our bonds in the open market to the best bidder.

The physicians informed Mayor Armstrong that the proposed plan would not appreciably increase city taxes, that the city indirectly is paying for PWA projects elsewhere and that no special election is needed to carry out the program.

Putnam County

DR JOHN T. JENKINS, secretary of the Putnam County Medical Society, reports that the society met at the Carmel Country Club on Sept. 2, and listened to a medico-legal program. The guest speakers were Judge James W. Bailey and District Attorney John P. Donohoe.

Queens County

DURING THE WEEK OF September 29 the Medical Society of the County of Queens will hold its Annual Meeting in conjunction with the Queensborough Tuberculosis and Health Association.

A particular feature of this meeting will be an exhibit on Tuberculosis which will include the history, development of the disease, method of prevention, and methods of cure, prepared for lay people and this exhibit is to be open during the entire week. The exhibit will include models, pictures, posters, actual bacteriological equipment, books, and magazines and will be constantly attended by demonstrators to explain the exhibit. The exhibit is being widely advertised by direct house to house.

advertising by various agencies and by radio talks each week, and a large representation of the public of Queens County is expected to attend

THE EXECUTIVE BOARD of the Queens County Cancer Committee, a branch of the American Society for the Control of Cancer, mapped plans for an active fall and winter season at its meeting in August in the Medical Society Building, 112-25 Queens Blvd, Forest Hills

Letters are being sent by the committee to 150 schools and a large number of mothers' clubs, church organizations, and civic and political groups in Queens offering speakers from the Queens County Cancer Committee in its educational campaign

Suffolk County

AT A RECENT MEETING of the Suffolk County Medical Society a resolution providing for a fee of \$5 for examining persons suspected of driving cars while intoxicated was unanimously adopted

It is pointed out in the resolution that heretofore a widely divergent fee was

charged and that the services of physicians in making these examinations and issuing certificates are partly voluntary and not compulsory and

"Whereas, The inconvenience and frequently extended court hearings resulting from the rendering of certificates of intoxication are a serious interference to the active practice of medicine, therefore be it

"Resolved, That the Suffolk County Medical Society go on record as favoring a minimum fee of \$5 for all such examinations whether or not a certificate is rendered and that a copy of this resolution be mailed to the Supervisors of each township and the Mayors or other heads of village governments"

Tioga County

DR. IVAN N PETERSON, Secretary of the Medical Society of the County of Tioga, reports that the Fall Outing Meeting of the Society will be held Sept 29, at Waverly. This will be a dinner meeting to which the ladies are invited and will be entertained by a musical program and an entertainer. The business to be transacted is the nomination of officers for 1937

PERILOUS FUMES OF CHROMIUM PLATING

An added danger to workmen in the toxic fumes given off in chromium plating, an industry introduced in 1927, was revealed on Aug 26 by Dr Lawrence T Fairhall, Assistant Professor of Physiology at Harvard, in an address before the health symposium at the Harvard School of Public Health

Painful skin afflictions, known as "chrome ulcers," caused by the action of compounds of chromium on broken places in the skin, were said to be a dangerous result of the great increase in chromium plating

More than half of the men engaged in the industry, Dr Fairhall declared, are also suffering from perforation of the membrane of the nose caused by the fumes inhaled while at work. These afflictions were said to be difficult to cure and take months to heal

"Dust injury from exposure to chromium

in industry," he stated, "is largely confined to dust from handling chromates or to spray from chrome-plating vats. Other processes in which workers are affected are those in which the skin comes into contact with a liquor as in tanning vats or in dyeing, rather than exposure to a dust."

The chromium worker is exposed to spray or mist carried into the air by bursting bubbles over the plating vats, he said, adding that because of the rapidity with which ulcerations appear, the labor turnover in this industry is said to be high

Dr Fairhall's address was on the general subject of poisonous dusts and fumes. He declared that by inhalation the entire circulatory system may be involved, whereas poisonous substances in the intestines are blocked by the kidneys and liver

DEPENDS ON THE SEX OF THE MAN

Quoting a statement that "a healthy well-nourished man can live from fifty to seventy-five days without food, provided he is not exposed to severe cold, avoids physical work, and keeps his mental calm," the

Medical Record remarks in an impressive display of sagacity that "it may thus be inferred that the length of time during which a man may live without food depends on height, weight, age, and sex"

A surgeon was forced to resort to the courts to collect his fee from a recalcitrant client

The counsel for the defense brought out the fact that the operation was performed in fifteen minutes

"The labor of fifteen minutes, then, is that for which you ask one hundred and fifty dollars?"

"No," the surgeon replied, "I ask it for the knowledge of a lifetime."—Commentator of the Owensby Clinic, Atlanta, June, 1936

LORENZ J. BROSNAN, ESQ

Counsel, Medical Society of the State of New York

Malpractice—Plaintiff's Failure to Prove Negligence

Recently the Court of Appeals in a nearby jurisdiction exonerated a physician of charges of malpractice in a typical case in which the claim was made based upon the treatment of a fracture.*

The plaintiff in the case was a single woman employed as a typist who brought suit against Dr. B. charging in her complaint that he had been engaged to treat a fracture of the bones of her left arm, but that he had improperly set the fracture, and had improperly removed the splint from her arm and discharged her at a time when the fracture was not properly set or healed.

Upon the trial of the action the plaintiff described having been injured when a street car on which she was riding came into collision with a truck. She had promptly consulted a Dr. L. who had treated her on certain occasions, and then ten days after the accident, she claimed to have become dissatisfied with his treatment, at which time she consulted Dr. B. She did not tell Dr. B. about the previous treatment, but he took x-rays and reported to her that "the end of the bone was broken off." The arm was set and wooden splints applied from the elbow to the wrist. The doctor took no further x-rays of the arm. According to her testimony, the plaintiff about three weeks after first visiting Dr. B., told him of an accident to her right arm some years before Dr. B. she said, thereupon told her that she had got the arms mixed and that the fracture shown in the x-ray was an old fracture. He then took off the splints and discharged her. She claimed that since her alleged accident she had been unable to operate a typewriter. She also told of consulting other doctors at a considerably later period who had administered baking and massage.

Cross-examination elicited from her the fact that Dr. L., a specialist in orthopedic work, had not treated her for a fractured arm but for contusions and lacerations. She also admitted that before Dr. B. discharged her a second set of x-rays was taken by certain roentgenologists.

The plaintiff called as a witness a certain Dr. W. and it appeared that he had made certain examinations of her nearly three years after Dr. B.'s treatment. He said that he found no difficulty in determining the

presence of a fracture, and that it was at the end of the ulna, but he could not say definitely how old it was. He conceded that it might have been from five to twenty years old. Dr. W. was asked to assume that there was a fracture when Dr. B. saw the case, and upon that assumption he testified that splints or a cast should have been applied, x-rays taken to check on the position, and the splints or cast allowed to remain for from four to six weeks. He testified that assuming the splints were removed at the end of three weeks, the plaintiff should not then have been discharged as cured.

On cross-examination Dr. W. further conceded that the x-rays showed a fracture which might have occurred years before the claimed accident, but he insisted that on Dr. B.'s x-rays, the arm at that time required a splint or cast, although he was somewhat vague as to the length of time the cast or splint should remain in place.

Dr. B., the defendant, took the stand and gave his version of the case. He described finding a condition of swelling above the wrist with some thickness of the wrist. He had, he said, continued to treat the case for about a month at the end of which time the plaintiff could move her wrist in all directions. Dr. B. gave the opinion that there was no fracture as recent as the alleged accident but that there was an old fracture which was a matter of years or months, but not of days.

Dr. L., who had preceded Dr. B. in the treatment of the patient, admitted when called as a witness that he had diagnosed a contusion on the forearm and had treated her for about ten days, applying bandages.

The roentgenologist to whom Dr. B. had referred the plaintiff gave testimony to the effect that x-rays taken in his office three weeks after the plaintiff's "accident" had revealed an old Colles' fracture of the left wrist and a normal right wrist.

Certain other doctors were called by the defendant all of whom supported his version of the problem, and expressed the opinion that the x-rays and history of the case showed that the fracture was an old one and required treatment for no longer a period of time than the defendant had actually accorded to it.

At the close of all the evidence a motion was made on behalf of the defendant doctor

*Wilson v. Borden, 32 Fed. 2nd 394

advertising by various agencies and by radio talks each week, and a large representation of the public of Queens County is expected to attend

THE EXECUTIVE BOARD of the Queens County Cancer Committee, a branch of the American Society for the Control of Cancer, mapped plans for an active fall and winter season at its meeting in August in the Medical Society Building, 112-25 Queens Blvd, Forest Hills

Letters are being sent by the committee to 150 schools and a large number of mothers' clubs, church organizations, and civic and political groups in Queens offering speakers from the Queens County Cancer Committee in its educational campaign

Suffolk County

AT A RECENT MEETING of the Suffolk County Medical Society a resolution providing for a fee of \$5 for examining persons suspected of driving cars while intoxicated was unanimously adopted

It is pointed out in the resolution that heretofore a widely divergent fee was

charged and that the services of physicians in making these examinations and issuing certificates are partly voluntary and not compulsory and

"Whereas, The inconvenience and frequently extended court hearings resulting from the rendering of certificates of intoxication are a serious interference to the active practice of medicine, therefore be it

"Resolved, That the Suffolk County Medical Society go on record as favoring a minimum fee of \$5 for all such examinations whether or not a certificate is rendered and that a copy of this resolution be mailed to the Supervisors of each township and the Mayors or other heads of village governments"

Tioga County

DR. IVAN N PETERSON, Secretary of the Medical Society of the County of Tioga, reports that the Fall Outing Meeting of the Society will be held Sept 29, at Waverly. This will be a dinner meeting to which the ladies are invited and will be entertained by a musical program and an entertainer. The business to be transacted is the nomination of officers for 1937

PERILOUS FUMES OF CHROMIUM PLATING

An added danger to workmen in the toxic fumes given off in chromium plating, an industry introduced in 1927, was revealed on Aug 26 by Dr Lawrence T Fairhall, Assistant Professor of Physiology at Harvard, in an address before the health symposium at the Harvard School of Public Health

Painful skin afflictions, known as "chrome ulcers," caused by the action of compounds of chromium on broken places in the skin, were said to be a dangerous result of the great increase in chromium plating

More than half of the men engaged in the industry, Dr Fairhall declared, are also suffering from perforation of the membrane of the nose caused by the fumes inhaled while at work. These afflictions were said to be difficult to cure and take months to heal

"Dust injury from exposure to chromium

in industry," he stated, "is largely confined to dust from handling chromates or to spray from chrome-plating vats. Other processes in which workers are affected are those in which the skin comes into contact with a liquor as in tanning vats or in dyeing, rather than exposure to a dust."

The chromium worker is exposed to spray or mist carried into the air by bursting bubbles over the plating vats, he said, adding that because of the rapidity with which ulcerations appear, the labor turnover in this industry is said to be high

Dr Fairhall's address was on the general subject of poisonous dusts and fumes. He declared that by inhalation the entire circulatory system may be involved, whereas poisonous substances in the intestines are blocked by the kidneys and liver

DEPENDS ON THE SEX OF THE MAN

Quoting a statement that "a healthy, well-nourished man can live from fifty to seventy-five days without food, provided he is not exposed to severe cold, avoids physical work, and keeps his mental calm," the

Medical Record remarks in an impressive display of sagacity that "it may thus be inferred that the length of time during which a man may live without food depends on height, weight, age, and sex"

A surgeon was forced to resort to the courts in order to collect his fee from a recalcitrant client.

The counsel for the defense brought out the fact that the operation was performed in fifteen minutes

"The labor of fifteen minutes, then, is that for which you ask one hundred and fifty dollars?"

"No," the surgeon replied, "I ask it for the knowledge of a lifetime."—Commentator of the Owensby Clinic, Atlanta, June, 1936

Across the Desk

Is the Medical Profession "Too Conservative?"

THIS CRITICISM PROBABLY STARTED when the first really scientific medical "dawn-man" refused to endorse the hocus-pocus of the tribal voodoo and mumbo-jumbo performers. And it has kept right on down to the present day. It is the main stock-in-trade of every "irregular healer," and of every pharmaceutical manufacturer who cannot get his wares accepted by the official authorities of organized medicine.

"The doctors oppose me because they are jealous of my success," says the quack "healer" while the drug manufacturer charges that "the doctors are too conservative and backward to recognize my marvelous discovery." The continuous dinging of this complaint into the public's ear of course could not help making at least some impression and credulous people here and there swallow it whole. A few weeks ago, even a staff writer in a Tennessee newspaper came out with an article taking the medical profession to task for its conservatism and slowness in accepting new ideas. Ask the ordinary man in the street what he thinks about it, and you will find more than a few who believe that the profession tends to lag a little behind the rapid advance of scientific progress.

Everyone within the profession knows that exactly the opposite is the fact, but the problem is to convince the public of it. Medical writers and radio speakers have a subject here ready to their hand, and the message of truth is timely and needed. A striking instance of the profession's readiness to adopt a new discovery was its prompt acceptance of insulin, as soon as its value was proven. Liver extract for anemia, too, was welcomed the moment it proved its worth. In fact, instead of being backward, the profession occasionally errs in being too eager, as in its use of vaccine for infantile paralysis. In such a case, it is frank and honest in acknowledging its error. On December 27 last Dr. William Hallock Park said, as quoted in these pages:

"I am still hopeful, but no longer confident, about the ultimate success of any vaccine to prevent paralysis."

Contrast that with the persistent claims of the charlatan, who keeps on proclaiming miraculous cures long after his remedy has been proved worthless.

The Profession is merely "from Missouri"

What is more, instead of blocking progress, the profession on the contrary continually pushes and encourages research and discovery. The A.M.A. gives awards and pays money every year to men who produce finds that are new and valuable. An entire department, the Council on Pharmacy and Chemistry, does nothing else but investigate new remedies, promptly approve those that are of value, and disapprove those that are not. Fraudulent claims in advertising get a sharp crack over the knuckles. What more could Mr. Critic ask? The Council, too, has not hesitated to enter the courts, like the humblest citizen, when its action has been challenged, and to date it has not lost a single case even before a jury of laymen. There you have a record to stand four square against all the winds of criticism from the foes of organized medicine.

There is something symbolical, perhaps in the fact that the annual meeting of the A.M.A. this year was held in Missouri. The profession "has to be shown." It is "from Missouri," when it comes to accepting new remedies. The ordinary man can understand and approve a thing like that. Anybody in the world can see the need of care and caution in testing the literally hundreds of new remedies brought out every year, some good, some bad, many of them touted with wild claims that run beyond all reason. The quack cancer "cures" alone would wreak untold havoc if no body existed to curb them.

The very drugs used daily by the physician are capable of great harm in unskilled hands, and some authority is needed to weed out the bad compounds from the good. "The most effective way to destroy progress," truly remarks the editor of the *Journal of the Tennessee State Medical Association*,

for a directed verdict, and the motion was granted by the Court. An appeal was taken from the judgment. The Appellate Court after considering the case affirmed the ruling of the lower Court, thereby finding that the evidence did not justify a submission of any issues to the jury.

In so finding the Court said in its opinion

In the present case all the medical testimony is to the effect that the injury of which plaintiff complained when she consulted Dr. B. involved an old Colles' fracture. Dr. W. for the plaintiff, testified that "fractures are always put up in splints or a cast." In his opinion the splints in the present case should have been allowed to remain on from four to six weeks. Assuming that the splints were allowed to remain on only three weeks, he did not think plaintiff should have been discharged as cured. The doctor did not state what further treatment plaintiff should have received before being discharged. While he ventured the suggestion that "an operation might have helped her" he admitted that he would not have operated. The nebulous character of Dr. W.'s testimony is apparent. He states that he would have set the arm with splints or a cast and allowed the splints or cast to remain for some time. That is precisely what was done. While in his opinion the splints should have been allowed to remain on from four to six weeks, other surgeons, equally skilled, testified that it would have been unwise to have left the splints on longer than from two to three weeks.

*There is no dispute that the splints were taken down once a week and the arm examined. It also clearly appears that before the splints were finally removed x-ray pictures of the arm were taken by experts in that art, and those pictures are in evidence. When these pictures were taken, the splints had been on for more than two weeks. It is significant that there is no testimony that these pictures disclosed anything that would form a basis for a charge of negligence or unskillfulness on the part of the defendant. Plaintiff's evidence may have tended to prove that her arm upon her discharge by defendant was in an unsatisfactory condition, but assuming it did that would establish "neither the neglect and unskillfulness of the treatment, nor the causal connection between it and the unfortunate event." All that was required of defendant in undertaking to treat the plaintiff was that he exercise the ordinary care and skill of his profession. * * * Plaintiff alleged lack of skill and negligence. She proved neither.*

Amputation of Leg

A man about forty years of age, an inmate of a County Jail, was found by the

physician of that institution to be suffering from a recurrence of a case of chronic osteomyelitis. He was referred to a Municipal Hospital where he came under the care of a physician specializing in orthopedic surgery. The doctor made an examination of him and found that his left femur showed evidence of an acute exacerbation of a chronic osteomyelitis, going back more than ten years and that nine operations had been performed upon the leg for the correction of the condition. The doctor ordered complete rest in bed, elevation of the leg, and continuous wet dressings. He saw him from time to time and the man's condition became worse, and at the end of a week he advised that the femur be curetted for the purpose of removing diseased tissue, in an attempt to arrest the spread of osteomyelitis. Consent to an operation was obtained and it was performed, after which the patient was returned to bed with a plaster cast and drains. The doctor continued caring for the patient, and at the end of ten days decided that the operation had not been successful in checking the spread of the condition and decided that unless radical steps were taken general sepsis would develop and cause the patient's death. The patient was told the doctor's recommendations and consented to amputation of the leg which the defendant proceeded to do, amputating the leg in the region of the lower third of the femur, removing what in his opinion, at the time, was all of the diseased bone.

The doctor further continued the care of the case and a week after the amputation, after obtaining consent to an operation performed another operation removing further portions of the bone. The patient's condition then became better and he was finally discharged from the hospital and sent back to jail.

Thereafter an action was instituted against the defendant in which a charge was made that the defendant had amputated the leg without consent of the patient and further that the cast had been improperly applied so as to cause extensive swelling and gangrene.

The case came on for trial before a Judge and a Jury and at the close of the plaintiff's case was dismissed on motion of counsel for the defendant doctor thereby determining that the plaintiff had failed to prove a cause of action against him.

A cash award of \$1,000 is offered by The Williams & Wilkins Company of Baltimore for the best manuscript on a science subject, presented before July 1, 1937. The publishers put no limitations on the subject-matter or manner of handling, and none

on eligibility for the award. The manuscript must be in English and "of a sort calculated to appeal to the taste of the public at large." The desired length is given as 100,000 words. Further details may be had by addressing the publishers.

To Put Pressure on the Pressure-Fakirs

A RATHER GOOD WAY is suggested to put the pressure on the fakirs who run blood-pressure reading devices at Coney Island and other resorts. The arrests and court proceedings may or may not prove effective. For ways that are dark, and tricks that are vain, the law, like Bret Harte's heathen Chinee, is peculiar. The suggestion is that physicians report any unfortunate results that

may happen from these ignorant and blundering attempts to make tests that only a doctor is qualified to perform and interpret. Reports of that sort are something concrete, something that people will pass along by word of mouth, and that will quickly give the fakirs the reputation they deserve. This department will be glad to cooperate in any way possible.

"Doctor"—of What?

OREGON HAS A LAW so clear and simple that the very statement of it is a sufficient commendation. It provides that anyone who uses the title "doctor" shall designate after

his name the kind of "doctor" he is. What could be fairer than that? It might be worth bringing to the notice of the next session of the legislature.

Books

Books for review should be sent directly to the Book Review Department at 1313 Bedford Avenue, Brooklyn, N. Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

ORDERING BOOKS

As a service exclusive to our readers, books published in this country may be ordered through the Business and Editorial Offices of the Journal (33 W. 42nd St., N. Y. C.) postage prepaid. Order must be accompanied by remittance covering published price.

RECEIVED

The Technique of Contraception. By Eric M. Matsner, M. D. Third edition. Octavo of 40 pages, illustrated. Baltimore, Williams & Wilkins Company 1936. Paper, \$50.

Diseases of the Respiratory Tract. Eighth Annual Graduate Fortnight of the New York Academy of Medicine. Octavo of 418 pages, illustrated. Philadelphia, W. B. Saunders Company 1936. Cloth, \$5.50.

Passive Vascular Exercises and the Conservative Management of Obliterative Arterial Diseases of the Extremities. By Louis G. Herrmann, M. D. Octavo of 288 pages, illustrated. Philadelphia, J. B. Lippincott Company 1936. Cloth, \$4.00.

The Study of Anatomy. Written for the Medical Student. By S. E. Whittall, M. D. Third edition. Duodecimo of 113 pages. Baltimore, William Wood and Company 1936. Cloth, \$1.75.

Collected Papers of the Mayo Clinic and the Mayo Foundation. Edited by Richard M. Hewitt, M. D., Lloyd G. Potter and A. B. Neyling, M. D. Volume 27, 1935. Octavo of 1353 pages illustrated. Philadelphia, W. B. Saunders Company 1936. Cloth, \$12.00.

Diseases of the Nose, Throat and Ear for Practitioners and Students. Edited by A. Logan Turner, M. D. Fourth edition, revised and enlarged. Octavo of 473 pages, illustrated. Baltimore, William Wood and Company 1936. Cloth, \$6.00.

Urology in Women. A Handbook of Urinary Diseases in the Female Sex. By E. Catherine Lewis, M. S. Second Edition. Octavo of 100 pages, illustrated. Baltimore, William Wood and Company 1936. Cloth, \$2.25.

The Extra-Ocular Muscles. A Clinical Study of Normal and Abnormal Ocular Motility. By Luther C. Peter, M. D. Second edition. Octavo of 351 pages, illustrated. Philadelphia, Lea & Febiger 1936. Cloth, \$4.50.

A Textbook of Histology. By Joseph Kraska, Jr., M. D. Octavo of 246 pages, illustrated. Baltimore, The Williams & Wilkins Company 1936. Cloth, \$2.50.

Your Breath and Your Health. By Louis M. Pearlman, M. D. Octavo of 128 pages illustrated. New York, Academy Publishing Company 1936. Cloth, \$1.00.

"would be to accept every wild-eyed scheme and put it into use without the proper tests and criticism"

Not a Pleasant Picture

Let us suppose for a moment that under some new political regime of the future all this sort of thing is put into the hands of a government department and is managed as other matters are managed at Washington. This is not such a wild supposition, either, for it might easily occur under a scheme of socialized medicine. What would happen then? Well, we can gather some idea from the ghastly farce that has been played with the Pure Food and Drug Bill, which has been so battered and tattered and torn and harried and chevied that its best friends were glad it did not pass.

Heaven help any measure framed to protect the public health that incurs the hostility and ferocity of moneyed interests that would like to see it die. Even the dullest imagination can grasp what a Council on Pharmacy and Chemistry would be like if under the thumb of a political party manager. A thousand times better to have it precisely where it is now, under the control of the profession interested in the public's health.

Dizzying Deluge of Discoveries

Another consideration, too, makes it imperative to have a central authoritative medical body pass on new products. Science is flooding the world with a dizzying cataract of new discoveries in every field—in mechanics, physics, chemistry, biology, physiology. Confusion and error are perhaps no more than natural in the mind that tries to grasp them all. Or, in the words of a medical writer of the Far West, "the poor credulous physician spins round like a pup chasing his caudal appendage in his futile efforts to keep up with the procession." This writer, Dr. A. B. Cooke of Los Angeles, goes on to say in *California and Western Medicine*:

New hormones, vitamins, and all kinds of fantastic panaceas, singly and in impossible combinations, released in ever-increasing number by laboratory technician and trade organization, have become perfectly bewildering in their number and variety. Today the profusion of remedies bears close resemblance to a tropical jungle, with its lush undergrowth concealing and smothering the occasional beautiful orchid.

No human mind is competent to remember and intelligently apply the resultant conglomeration. A heterogeneous mess of good, bad, indif-

ferent, and actually harmful, is thrust upon, and threatens literally to engulf us. Aneidemin, karcin, panodyn, jeculin, ineretone, sedobrol, glykeron, pneumophthisin, ergoapiol, endocrine compound No. 4 (or 404), anti-this and pro-that, etc., *ad nauseam et ad infinitum*. These, cited at random, are a few, a very few, of the fancifully named products that we are besought and instructed, at the sacrifice of much of our office time, to bear in mind and perpetrate upon our confiding patients. And the crop seems inexhaustible. The total cost involved in printing, postage, samples, and salaries would undoubtedly make a considerable dent annually in our huge national debt. Somebody must pay this cost. Trade does not operate on a philanthropic basis.

Beware of Hasty Bouquets

The unfortunate result that may happen when a physician is unwise enough to endorse one of these preparations, without waiting for the verdict of the A. M. A. or without a full and proper investigation of his own, was revealed in a recent trial. The Government was defeated in its attempt to prove that a certain manufacturer of an herb tea was guilty of fraud under the criminal clause of the Food and Drugs Act because two witnesses, a doctor and a layman, had written complimentary letters to him about his product.

In vain did these witnesses testify that they were misled, that they had found the tea worthless. The manufacturer declared that he depended upon their letters as endorsements, so the jury decided that he had no fraudulent intent. This case "should serve as a warning to the physician against haste in judgment of therapeutic results," remarks the *A. M. A. Journal*. Doctors are misled by "hasty enthusiasms," and "then, like the ghost in 'Hamlet,' their testimonials come back in later years to haunt them."

A New Library—of Charlatanry

A whole library is growing up on the subject of fake cures, treatments, and nostrums, and it is not at all a bad idea for a doctor to have some of this literature in his library, or, in fact, on the table in his waiting room, where it will help spread the much-needed gospel of honest medicine. County medical societies may wish to include this colorful and newsy subject in their medical broadcasts during the coming fall and winter. Here is a list of some of the booklets, full of good material, which are to be had from the American Medical Association, 535 North Dearborn St., Chicago:

book adapted for students taking the subject for the first time, and in this effort to present the subject in a condensed form without omitting any essentials, the author has succeeded admirably

However, this reviewer believes that this very brevity militates against the use of the book for medical students and physicians, because the detailed studies which such a reader would seek are not to be found here

I COHEN

The Radiology of Bones and Joints By James F Brailsford, M D Second edition Quarto of 571 pages, illustrated Baltimore, William Wood & Company, 1935 Cloth, \$9 00

The second edition of this book, appearing one year after the original, at once bespeaks its value It is indeed a well written addition to medical literature.

The author stresses the importance of periodic X-ray studies, and the necessity of the Radiologist taking a clinical interest as well as specializing in execution and interpretation of the films

The various traumatic and diseased states that the skeleton may fall heir to are described, so that bone pathology is quite completely and well covered. There are three hundred and forty illustrations, including many tracings which clarify otherwise obscure findings, and the X-ray photographs are well chosen and of good quality The book abounds in references, there being a bibliography of twenty-seven pages

For the orthopedist it should prove of great value, for those in industrial practice it will help clarify many doubtful cases, and for the radiologist it is a storehouse of information

MILTON G WASCH

Fasciae of the Human Body and Their Relations to the Organs They Envelop By Edward Singer, M D Quarto of 105 pages, illustrated Baltimore Williams & Wilkins Company, 1935 Cloth, \$3 00

This volume is apparently a continuation of the work of fascia planes which was presented as a small monograph by the late Dr B B Gallaudet in 1931, and which we had the pleasure of reviewing

The surgical work during the past few years has created a great deal more attention toward the various fascia planes of the body, and the work of Dr Gallaudet and this more comprehensive volume of Dr Singer's fulfills a much needed want.

The method of dissecting the fascia, enveloping the organs, which is the one used by Dr Singer, is somewhat unique and gives one a more comprehensive idea of the fascial layers and their relationship

The 24 original illustrations by Elizabeth Cuzzort are excellent and exceedingly beneficial in visualizing the concise text of Dr Singer

This is an excellent volume for the student of anatomy, regardless of his interest in the fascial planes of the body

HERBERT T WIKLE

For and Against Doctors. An Anthology compiled by Robert Hutchison and G M Wauchope Duodecimo of 168 pages Baltimore, William Wood & Company, 1935 Cloth, \$2 00

This little book of 168 pages is comprised of a foreword, the Oath of Hippocrates and six chapters, as follows I Proverbs II The Ancients III Medieval IV Fifteenth to Seventeenth Centuries V The Eighteenth Century VI The Moderns A Retrospect. It is replete with interesting proverbs and excerpts, reflecting the lay opinion regarding the skill and competence of physicians throughout the ages of recorded history These excerpts represent the views of great thinkers in different historical periods They are impersonal and, on the whole, frankly condemn the doctor, his helpless attitude towards disease, and lively interest in the commercial side of his profession (sic!) There are a minority of noble tributes The book is full of atmosphere and evidences scholarship on the part of the authors To those interested in medical history and the general relationship between the public and the doctor, it must prove both fascinating and educational

J M VAN COTT

The Early Diagnosis of the Acute Abdomen. By Zachary Cope, M D Seventh edition Octavo of 254 pages, illustrated New York, Oxford University Press 1935 Cloth, \$3 75

This book now in its seventh edition deserves a prominent place on the preferred shelf of every practising physician, regardless of whether he be general practitioner or specialist The difficulties of diagnostic criteria in acute abdominal conditions are extremely well covered. The author stresses the importance of early, careful diagnosis as against "spot diagnosis" or morphine delay. The oft repeated necessity for rectal examination is mentioned The importance of shoulder pain, particularly on the right side, in the differentiation of lesions affecting the right diaphragm is discussed An interesting note is made of the fact that a normal pulse does not necessarily mean a normal abdomen. In his discussion of acute appendicitis, he notes the fact that an appendix may be all but perforated without local

International Clinics A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment, Medicine, Surgery, Neurology, etc Edited by Louis Hamman, M D Volume 2, 46th Series, 1936 Octavo of 327 pages, illustrated Philadelphia J B Lippincott Company 1936 Cloth, \$3 00

Security Against Sickness A Study of Health Insurance By I S Falk Octavo of 423 pages Garden City Doubleday, Doran & Company, Inc 1936 Cloth, \$4 00

Post-Graduate Surgery Edited by Rodney Mangot, F R C S Volume II Quarto, illustrated New York, D Appleton-Century Company 1936 Cloth, \$45 00 for set of three volumes

Exophthalmic Goiter and Its Medical Treatment. By Israel Bram, M D Second edition Octavo of 456 pages, illustrated St Louis, C V Mosby Company 1936 Cloth, \$6 00

Principles and Practice of Recreational Therapy for the Mentally Ill By John E Davis, B A Octavo of 206 pages New York, A S Barnes & Company 1936 Cloth, \$3 00

Mental Nursing (Simplified) By O P Napier Pearn, M R C S Second edition 16mo of 328 pages, illustrated Baltimore William Wood and Company 1936 Cloth, \$2 00

Minor Surgery By Frederick Christopher, M D Third edition, reset Octavo of 1030 pages, illustrated Philadelphia, W B Saunders Company 1936 Cloth, \$10 00

Methods of Tissue Culture in Vitro by Ralph Buchsbaum, Ph D, and **Outlines of Histological Methods with Special Reference to Tissue Culture** by Clayton G Loosli, Ph D Octavo of 81 pages, illustrated Chicago, University of Chicago Press 1936 Paper, \$1 00

The Eye and Its Diseases By 82 International Authorities Edited by Conrad Berens, M D Octavo of 1254 pages, illustrated Philadelphia, W B Saunders Company 1936 Cloth, \$12 00

Disability Evaluation Principles of Treatment of Compensable Injuries By Earl D McBride, M D Octavo of 623 pages, illustrated Philadelphia, J B Lippincott Company 1936 Cloth, \$8 00

Pathological Physiology and Clinical Description of the Anemias By William B Castle, M D & George R Minot, M D Edited by Henry A Christian, M D Octavo of 205 pages New York Oxford University Press 1936 Cloth, \$3 00

The Toxaemias of Pregnancy By Dame Louise McIlroy M D Octavo of 355 pages Baltimore, William Wood & Company 1936 Cloth, \$5 00

REVIEWS

International Clinics A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment, Medicine, Surgery, Neurology, etc Volume 4, 45th Series, 1935 Edited by Louis Hamman, M D Octavo of 331 pages, illustrated Philadelphia J B Lippincott Company, 1935 Cloth, \$3 00

The first article by J H Means is on "Observation of the Tongue and What it Teaches Us about the Patient's General Condition" The dry tongue, the smooth tongue and the large tongue, the last often suggesting myxedema are the main types considered "Idiopathic Steatorrhea," "Aleukemic Leukemia" called as preferred by the author "Hypocytic Leukemia," "Anemia in Pregnancy," and "The Treatment of Diabetes Mellitus" are some of the other articles

In an article on the use of bacterial vaccines, P H Long of Johns Hopkins discusses the subject in a conservative manner He finds that typhoid vaccine is the only one that fulfills the requirements of an efficient bacterial immunizing agent He concludes that the use of Streptococcal vaccines in the treatment of rheumatoid arthritis produces only results that are uncertain and contradictory

There are other interesting articles, especially the one on Lymphogranuloma Inguinale with a preliminary report of 136

cases and a review of the literature of the subject which seems to be very complete, consisting of 371 references This is written by C F Martin and H E Bacon of the University of Pennsylvania

W E McCOLLUM

Regional Anatomy By J C Hayner M D Octavo of 687 pages Baltimore, William Wood & Company, 1935 Cloth, \$6 00

This anatomy is designed as a dissection manual and is arranged in regional order This arrangement is a decided improvement over the usual structure of a textbook. The presentation is very clear and concise without giving it, however, the character of a compend

The complete absence of diagrams and illustrations is of course, in accordance with its aim, but necessitates the use of an atlas when it is being used as a reference book For the mature surgeon it possesses many advantages over the accepted manuals of anatomy particularly in its size and comprehensiveness

GEORGE W FERR

A Textbook of Bacteriology By Thurman B Rice M D Octavo of 551 pages illustrated Philadelphia W B Saunders Company 1935 Cloth, \$5 00

This book is offered as a shorter text-

Adequate treatment of Pernicious Anemia

WITH A MINIMUM OF INCON-
VENIENCE TO THE PATIENT MAY
BE OBTAINED BY THE USE OF

1 cc. CONCENTRATED SOLUTION LIVER EXTRACT

Lederle

THE CHOICE OF A LIVER EXTRACT for the treatment of pernicious anemia should depend primarily on the potency of the extract. Since treatment must be continued at definite intervals, it is also important to consider the discomfort caused by the injection of the extract.

The newest of the *Lederle* parenteral preparations, 1 cc. CONCENTRATED SOLUTION LIVER EXTRACT, has now had nearly two years of clinical use. With this preparation it is possible to effectively treat pernicious anemia with a minimum of inconvenience to the patient.

Available only in boxes of 3 vials—each containing, in a volume of one cubic centimeter, active substance obtained from 100 grams of liver.

LEDERLE LABORATORIES, INC.
30 ROCKEFELLER PLAZA
NEW YORK, N. Y.

rigidity, and discusses the pitfalls very clearly, outlining the usual "march of events" His description of acute pancreatitis is excellent, also that of intestinal obstruction The section on colics will prove fascinating and important. The last chapter of the book on diseases which simulate the acute surgical abdomen completes a most interesting and valuable contribution to medical literature

BENJAMIN M BERNSTEIN

New Pathways for Children with Cerebral Palsy By Gladys G Rogers & Leah C Thomas Octavo of 167 pages, illustrated New York, The Macmillan Company, 1935 Cloth, \$2 50

This is a book for those specializing in the care and training of handicapped children While it deals specifically with the experiences and results of a camp for children suffering from all forms of cerebral palsies and birth injuries, it possesses many features which commend it to the examination of other, similarly situated, institutions (such as those for mental defectives) It is full of practical findings and suggestions for the handling of the emotional as well as the physical handicaps involved and shows how meeting the needs of these children in a simple way, permits them to be reared in a social environment suitable to their requirements and outlook as human beings

SAM PARKER

The Medical Treatment of Gallbladder Disease By Martin E Rehfuss, M D & Guy M Nelson, M D Octavo of 465 pages illustrated Philadelphia, W B Saunders Company, 1935 Cloth, \$5 50

In this book a distinguished clinician who is also a research worker, has made the fruits of his knowledge and experience available to the medical profession

The authors have produced a book which, in a concise manner brings order out of the chaos of medical thought frequently surrounding this problem

The diagnosis of gall bladder disease as based on history, bile examination (obtained by duodenal drainage) and by x-ray is discussed in detail The section on roentgen diagnosis is particularly helpful It is also interesting to note that the authors are definitely committed to the value of the duodenal tube, both in diagnosis and treatment of the many conditions affecting the gall bladder

Gall bladder disease is considered a secondary condition with three fundamental factors, namely—the metabolic problem, the problem of infection and the question of stasis Treatment is outlined in detail with these factors in mind The medical treatment advised includes diet, various forms of drug therapy, duodenal intubation, bacteriological methods, physiotherapy and mineral water therapy

A review of this book can hardly do justice to the wealth of information which it contains It deserves deliberative reading for the slow digestion of the innumerable practical and helpful facts which it offers

HENRY F KRAMER

The Modern Treatment of Burns and Scalds By Philip H Mitchiner, M D Octavo of 64 pages, illustrated Baltimore, William Wood & Company, 1935 Cloth, \$2 00

This small volume of sixty-four pages has been compactly written to illustrate the modern treatment of burns and scalds

There are six chapters which describe various methods of treating sunburn, electric, x-ray, radium, chemical, mustard gas, burns, etc It elaborates a great deal upon tannic acid treatment and covers in a fair way the causes leading to death in burns and scalds, with some account of the general principles on how to prevent and combat them

R F HARLOE

Aids to Medicine By James L Livingstone. Fifth edition 16mo of 422 pages Baltimore, William Wood & Company, 1935 Cloth, \$1 50

Five editions of this work attests its value as a useful volume for handy reference to medical students It covers the subject of medicine in fifteen chapters and is complete, thorough and inclusive as well as accurate It will prove a valuable volume for review and reference

HENRY M MOSES

Prescription Writing and Formulary By Charles Solomon, M D Octavo of 351 pages illustrated Philadelphia, J B Lippincott Company, 1935

So much emphasis has been put upon diagnosis and so little attention has been given to therapeutics and the action of remedies for pathological conditions that it is a pleasure to study this work by the author whose experience has taught him the necessity of more complete study and knowledge of drugs and their uses than is included in the curricula of many of the medical colleges Not only is this volume accurate, complete, concise, and carefully prepared and presented but it also contains interesting references to the history of prescription writing and drug using of those nations whose writings have been handed down to us

Examples are given in the methods of various procedures of medication with dosages and common errors frequently found in giving drugs A formulary, classified for systemic diseases, is presented with the most used formula Many of the valuable features can be found only after a careful study of this valuable work

CHARLES B. TOWNS HOSPITAL

**DRUG
and
ALCOHOLIC
SICKNESS**

This defines clearly our work with and for the physician — outlines it step by step from the time physician writes us about his alcoholic or drug patient. It shows what specific attentions, what needed emergency methods, are ready at the physician's command, for these mentally baffling cases. Methods—from detoxinizing to mental reconstruction—to returning an individual who cooperates with a will!

For your reference library — detailing the many means — the direction, equipment, environment at physician's disposal

ADVERTISERS!

The new 1937 issue of the **MEDICAL
DIRECTORY OF NEW YORK, NEW
JERSEY AND CONNECTICUT** now
being compiled will be 100 per cent
more valuable to the physicians of this
area for four reasons—

- 1 Under the amendments of the Work
men's Compensation Law of New
York State medical care is re-
stricted to authorized physicians.
These will be keyed in the 1937
issue.
- 2 Additional information to be pub-
lished on physicians' hospitals and
medical society of New Jersey.
- 3 Additional information to be pub-
lished in Connecticut section also.
- 4 Upward of 50 per cent of data on
physicians in all three states will
have revisions on addresses, phone
numbers and hospital connections.

For these reasons, every physician in the
three states will find it necessary to use
the new edition and to refer to it even
more often than before. Reason enough
for you to make sure that you do not
fail to—

The Demand for Culture

It is a significant fact of our times that society has had more or less of an overturn since the war Many who were prosperous are now living very plainly, and many whose fathers were wage-earners are now well-to-do and are in the "white collar" class We have been having an economic revolution One result is that almost every doctor has among his clientele families who wish their boys and girls to enjoy a culture which the father and mother never knew The parents are ambitious for their children, and often turn naturally to the family physician as guide, counselor, and friend The public school offers little in the way of culture, and the doctor is asked to recommend some private school where the children will be trained to mingle easily with refined people in the circles they hope to enter

It is impossible to exaggerate the feeling that fathers and mothers have for the future welfare of their girls and boys

Every parent likes to see his boy excel As one father once said, "It makes me feel as if my own life were worth while when I see my boy succeed Without that, all my own efforts would seem futile" Such a father asks himself questions like these

NORTHWEST INSTITUTE

A PROFESSION FOR
MEN AND WOMEN

"Have I really done all I could do to help that young fellow? Have I realized that perhaps he needs an opportunity of a different sort than I had? Or have I taken for granted that with his blood and parentage he must eventually succeed in a sink-or-swim struggle as his father did?"

Recent years have changed things in this world The old way of reaching the top doesn't seem to be quite as simple and established as it did a short time ago The social order grows daily more complicated—the boy grows more confused. Which way shall he turn?

The natural thing is to turn to a first-class school It is their work to take the raw colt of a boy and turn him into a clean-limbed thoroughbred

Travel and Resorts

Eliminating "Help" in Competition

A new note in staging a fair competition was introduced at the Atlantic City meet for national lifeguards championship last month

Dummies were used as "victims" instead of human beings. This according to Dr. Charles L. Bossert, veteran head of Atlantic City's Beach Patrol who was in charge of the arrangements, prevented either help or hinderance by human "victims" as heretofore experienced. It had been discovered, for instance, that when a lifeguard towed a man ashore, the purported victim could kick under water and help along—or could spread legs, cup hands at side, and so create a drag.

The substitute dummy, used for the first time this year in any competition of this sort, is made of a common canvas bag, loaded at one end with forty pounds of crushed stone. In the middle is placed an empty five-gallon oil can for buoyancy, and the other end is tied together in long slender forms like a man's arms. While not as realistic as the flesh and bone of a real human, the substitute is rather scientifically created and has the added advantage over the old arrangement, in that every "victim" is identical in size, shape, and weight which eliminates any chance of even a slight advantage in that respect.

The success of the above mentioned event as well as the Showman's Variety Jubilee, is now a matter of record, but the wind-up of the Summer season does not by any means close Atlantic City's attraction. Although but slightly over a hundred miles south of New York, the "World's Playground" has a surprisingly milder climate even during winter.

And for those who know what it is to enjoy the tang of the sea air over a weekend, there is probably nothing (less than a Florida vacation for which few of us can spare time) that can meet the pleasantness of one of Atlantic City's splendid hotels, attractions, and boardwalk in the Fall and Winter.

* * *

Through periodic and other medical examinations the railroads are prolonging the lives of their employees, and by medical treatment are reclaiming thousands who otherwise would have to be retired from active service.

* * *

By chemical treatment of water used in locomotive boilers, the life of a fire box and flues has been doubled and in many instances trebled.

Summer Sport in Chile — Skiing

The Ski Club of Chile reported a most successful season in the Corro Colorado district of the Las Condes Valley.

Travellers on Grace Line steamers back from a trip to that country, speak of July and August snowfalls as if such things were a common everyday summer affair. However, the Ski Club predicts these snowfalls will make September the usual best month for Chilean ski-runners.

The Ski Club's hut, at 7,200 feet above sea level dominates open ski fields (equal to the world's best) occupying an area of from 30 to 40 square miles. Slopes of all degrees permit practice runs or more exigent tests of expert skill.

Besides Las Condes, there is the Club Andino's grounds at Lagunillas, only three hours from Santiago, and the German Club is at Potrero Grande in beautiful skiing country. Further south at Chillan, the Ski Club of Concepcion and Chillan own a well equipped hut while enthusiasts who follow the sport in Switzerland, claim that the famous Parsenn course at Davos is commonplace in comparison to this area where one may stay a month and never repeat the same run. Two other clubs in the south are those at Osorno where the July snowfall is particularly heavy, and at Bariloche in the Lake District.

Skiing enthusiasts who are not members of these clubs, find admirable sport at Portillo on the Trans-Andine Railroad, five hours from Santiago. The run drops 2,700 feet from Portillo to Juncal, or one may climb to the Argentine border and run down over untracked snow from an altitude of 13,500 feet.

* * *

Memorial Highway Attracting Motorists to Lake Placid

The period from September 15 to the same date in October at Lake Placid is called "The Month of Flaming Leaves," when Nature's frost brush paints the trees and mountain foliage in gorgeous shades of red, yellow, and russet, transforming the whole region into a thing of vivid flame.

Sport and diversion are at their best during "The Month of Flaming Leaves." Members of the cottage and hotel colony take to the

bridle trails, the golf courses, the mountains, and the forests, where the keen air of early autumn gives a new zest to every activity

Attractive rates at hotels, clubs, and guest-houses through September and October appeal to the autumn-minded vacationist.

Motorists, in particular, are enthusiastic about the drive up Whiteface mountain at the head of Lake Placid over the new million-dollar Whiteface Mountain Memorial Highway. The clear air of early fall gives added length and beauty to every vista from this great peak, 4,872 feet above the level of the sea.

Work has already begun on the tunnel and elevator which will take sight-seers from the present end of the highway to the peak of the mountain. The tunnel enters the granite side wall 400 feet from the end of the road. It will be approximately five feet wide by seven feet high and will pierce the mountain on a slight incline for a distance of 424 feet.

From this point an elevator shaft will rise perpendicularly 273 feet, emerging by the fire tower on the summit of Whiteface 4,872 feet above the level of the sea.

Highway-Railroad Grade Crossing Accidents

Although there was a reduction in the number of accidents, there was an increase in the number of persons killed at highway-railroad grade crossings in May, this year, compared with the same month last year, the Safety Section of the Association of American Railroads announced today. The number injured was slightly below last year's figures.

Fatalities from grade crossing accidents in May, 1936, totaled 119, compared with 108 in the same month last year. The number of accidents reported was 247, a decrease of 29 compared with May, 1935, while the number of persons injured in those accidents was 285, or a decrease of 12 below the same month last year.

In the first five months of this year, fatalities resulting from accidents at highway-railroad grade crossings totaled 642 compared with 630 in the same period of 1935, or an increase of twelve. Persons injured totaled 2,002, compared with 1,884 in the first five months of 1935. The number of grade crossing accidents in the first five months this year was 1,674, an increase of 91 compared with the same period in 1935.

* * *

The railroads, particularly those in the South, have been among the leaders in bringing about the control of mosquitoes as a preventive measure against the spread of malaria and other diseases.

"Sea Torpedoes" Lure Motorists to Nova Scotia

Swimming north at the rate of a thousand miles a week, great schools of "thunnus thynnus" (tuna to you!) have been arriving during the month in the waters of Fundy Bay off Wedgeport and Yarmouth, and at Hubbard and Halifax on the Atlantic side of the province

Wedgeport is less than a half hour's pleasant motoring drive from the Lakeside Inn at Yarmouth, southwestern gateway to Nova Scotia and a well-known summer watering place. Wedgeport itself, being a small, French-Canadian fishing village populated almost entirely by the descendants of the ancient Acadians who returned after the expulsion of 1755, has no facilities for the entertainment of visiting motorists who usually make their base of operations at one of the inns on Milo Lake, northeast of Yarmouth

The Lobster Bay fishing grounds, near here, were "discovered" by Michael Lerner, New York sportsman, last September, who boated twenty-one tuna in eight days, the largest of which, a 450-pound specimen, was landed in 46 minutes and the smallest, a 95-pounder, was boated in three and one-half minutes

Information regarding the tuna grounds of Yarmouth is available at the Guides Association headquarters, South Wedgeport, at any Canadian Pacific hotel or at offices and agencies of the Dominion Atlantic Railway and the Eastern Steamship Company Yarmouth may be reached in 15 hours by boat from Boston, or 22 hours from New York City, or by a motor journey southwest from Digby and "The Pines" after a ferry trip across the Bay of Fundy from Saint John, N B The town site itself is historically interesting, having been discovered by the Vikings 500 years before Columbus landed in the West Indies Principal points of interest aside from the fishing in fresh and salt water, are the Public Library where the priceless Runic stone is kept, which gives the evidence of "Vineland's" early discovery, the Lakeside Inn the fishing villages, a splendid golf course and country club, and numerous picturesque drives through the moose and Virginia deer country

According to Mr Lerner, he has never seen more fish surfacing at one time than in the waters off Yarmouth "Not even tarpon at Boca Grande can compare", he adds, "or pollock at Montauk Point in May There were acres and acres of tuna Visualize if you will a fast running tide-rip, a mile in width and half as much in length, with great blue-fin tuna-fish of 100 to 600 pounds—playing and

(Continued on page xxxiv)

this mountainous and sparsely populated region, ideal for the climber, hiker or angler in pursuit of the lordly salmon. Its wild peaks include Ben Ime, Beinn Narnain and the Cobbler, and the magnificent hills of the country known ironically as "Argyll's Bowling Green." Lovely Loch Eck, Glen Masson, Glen Finart and little-known Glen Shellach, lie in its southern portion.

The angling fanatic may pass on to Lough Neagh and Lough Melvin in Ulster with their fighting trout, known to Northern Ireland as Dollaghans, Gillaroos and Sonaghans. Ulster's lakes and rivers teem with fish—its salmon and trout fishing are becoming famous. Parts of Britain are as wild as any land in the world, but the distances are short, and the adventurous traveler, reaching them by fast train or plane, need waste little of his precious time en route.

jumping, feeding on mackerel. The name of this newly found 'hot-spot' of the north is Soldier's Rip, situated about an hour's sail in a fish boat from Lower Wedgeport, which is 12 miles by a good automobile road from Yarmouth. The tuna feed around the many islands that comprise the Tusket group in Lobster Bay, going out with the ebb tide as far as the rip, which is only a few hundred feet from the outer islands."

A giant tuna weighing 956 pounds was taken in Nova Scotia waters in 1934, but every year tuna weighing as high as 1,500 pounds are harpooned and landed during the fishing season 'round Hubbard and Halifax. In the capital city parties are usually made up at the Lord Nelson Hotel, opposite the Public Gardens

"Roughing It" About Britain

The recent creation of a National Forest Park in Scotland is the latest concession to the Briton's love for roughing it. The new park, containing about one hundred square miles of one of the most beautiful and least known parts of the country, is divided into two parts by Loch Goil, an arm of the sea which, branching off from Loch Long and the Firth of Clyde, pierces the heart of the mountains.

There are scarcely any roads or trails in

★ On the board walk you get the real sea breeze, you slip on your swim suit in the hotel—in a step or two you are on the beach. You can sit on the sun deck and watch the world go by, a gay, colorful world at play and it costs no more at the

Special Tourist Rate of Exchange Features Italian Tourist Checks

Italian Tourist Checks can now be obtained from leading banks and tourist organizations

These are non-transferable orders in given denominations of 100, 250, and 500 Lire for independent travellers, and in blank form for any amount not exceeding 5,000 Lire for organized parties, and are exchangeable in Italy for Italian currency

There advantage is evident in a comparison of the rates of exchange The ordinary rate of exchange is \$7 90 for 100 Lire. The special tourist rate of exchange is \$6 05 per 100 Lire, and the checks are valid for six months

Complete information of the three plans offered through the Italian Tourist Checks, may be obtained from the Italian Tourist Information Office at Palazzo D'Italia, 626 Fifth Avenue, N Y, your travel agency or bank, or through the Travel Service Department of this JOURNAL

Ontario Woman Catches 30-lb Muskie

A O Seymour, general tourist agent of the Canadian Pacific Railway states that a 30-lb muscalunge, 4 ft. long and 17 inches in girth, has just been caught in the French River by Mrs T R Meredith of London, Ont This fish has been entered in the annual French River Bungalow Camp Trophy Competition, which will be decided this month Mrs Meredith, however, will be up against stiff competition, since Jack Strathdee, manager of the French River Camp, reports the biggest season in its history

Mr Seymour also reports that muskie fishing at the Lake of the Woods Muskie Camps at Kenora, Ont, has been exceptionally good this season The largest fish taken was a 42-pounder

**PROTECTION
THAT PROTECTS**

**THE BEST WARRANTY IS ONE THAT HAS
THE BEST MECHANISM TO GO WITH IT**

Westinghouse was first to give
five years' protection on all models.
But the best thing about the West-
inghouse warranty is that you need
so little. Best protection of all is
the dependable performance of the
Westinghouse Sealed-in Mechanism
... against annoying service inter-
ruptions ... food spoilage ... delays
which no warranty on earth can
over. That's what really saves you
money ... not just this week ... nor
this year ... but for years to come

ACID RESISTANCE

WITH

KALAK

Hypertonic—Alkaline—Carbonated—Not Laxative

The years of experience with physicians who have used Kalak show that the use of a formula containing calcium, magnesium, sodium and potassium salts represents a correctly balanced solution. This is Kalak which, as such, aids in maintaining a balanced base reserve.

How Alkaline Is Kalak?

One liter of Kalak requires more than 700 cc. N/10 HCl for neutralization of bases present as bicarbonates. Kalak is capable of neutralizing approximately three quarters its volume of decinormal hydrochloric acid.

Introducing Our New Ultra-Short Wave Apparatus

This impressive Garfield ULTRA-SHORT WAVE Apparatus, operated by a **SPARK GAP WHICH IS CONSTRUCTED DIFFERENTLY** from any other on the market, contributes beauty and prestige to a Doctor's office.

After months of research and experimentation by experts, the Garfield High Frequency Laboratories, Inc., have developed a Spark Gap which offers the physician a **SURPLUS OF POWER OUTPUT**

**THIS GAP IS CONSTRUCTED DIFFERENTLY
FROM ANY OTHER ON THE MARKET**

Among the many unique features of this most beautiful ULTRA-SHORT WAVE Machine are the following

A RESERVE OF POWER for air spaced electrodes giving specific thermal depth effect.

SMALLEST ELECTRODES may be used as effectively as the largest.

TREATMENT WITH THE INDUCTION COIL

CUTTING in which no metal indifferent electrode is required — cuts under water

PERFECT COAGULATION — both bipolar and monopolar

SIMPLIFIED DESICCATION

ARMS may be moved to any angle or position without the tightening of a single knot and are concealed when not in use.

COMPARTMENTS in which all electrodes may be hung and foot-switch and surgical outfit conveniently stored

SLIDING PANELS for treatment of extremities.

AUTOMATIC TIMER

OPTIONAL FINISH

AN INTRODUCTORY PRICE FAR BELOW ANYONE'S EXPECTATION

Equipped with ball-bearing casters

CHARLES BRANDON McNAIR

WANTED

in Florida where he was indicted by a Federal Grand Jury at Jacksonville, February 24, 1932, for concealing cash and merchandise from the Trustee of his estate in bankruptcy

KNOWN TO BE SUFFERING FROM PERNICIOUS ANEMIA and a TROPICAL DISEASE—he received treatment in N. Y. City during 1934 from either a Swiss Pathologist or a German Doctor. It is believed that he is still receiving treatment here part of which consists of a diet of raw fruits including strawberries and bananas and little or no water.

He is 36 years of age, 5 feet 6 inches, 170 lbs., pale complexion partly (but possibly has lost weight due to illness), gray hair getting bald on fore part giving effect of a very high forehead. American married (probably living with wife) two children—Charles B. McNair Jr. (address unknown), Mrs. M. B. (Octavia) Moore Jacksonville Fla. Squalid continuously and appears to be always smiling.

A Diagnostic Aid

Normal seminal vesicles. Radiograph following Lipiodol injection. The outline of the vasa deferentia is clearly visualized

INTUITION alone does not make a clever diagnostician. Instead, the modern physician utilizes every available clinical and laboratory device to arrive at a diagnosis.

In the past decade, Lipiodol radiography has come to the front as an essential technique in diagnosing certain types of diseases.

In the first place, Lipiodol radiography may throw light on conditions otherwise obscure, and makes possible the application of radiology to organs and tissues which ordinarily cannot be visualized, for example, the broncho-pulmonary

system, the female pelvic viscera, or the seminal vesicles.

In the second place, by means of Lipiodol radiography, it is possible to obtain clear cut, brilliant and conclusive radiographs in which the pathology is clearly defined and precisely demonstrated.

Lipiodol (Lafay) is the original French iodized oil. It represents an organic stable combination of 40% iodine with poppy-seed oil.

Lipiodol may be injected into numerous body tissues and cavities. It is slowly absorbed and slowly eliminated; it is relatively non-toxic and non-irritating.

INDICATIONS FOR LIPIODOL

Lipiodol may be advantageously used in the roentgenographic exploration of the following systems, with of course, proper consideration of suitable technique and contra-indications in each case:

- 1 Broncho pulmonary apparatus
- 2 Uterus and Fallopian tubes.
- 3 Paranasal sinuses
- 4 Bladder, urethra and seminal vesicles.
- 5 Lacrimal ducts
- 6 Fistulae and abscess cavities.

Lipiodol (Lafay)

Iodized Poppy Seed Oil 40%

COUNCIL ACCEPTED

Pocketbook wisdom—

Two salesmen start out to canvas the territory covered by the NEW YORK STATE JOURNAL OF MEDICINE

Both for a matter of example are equally capable—both equally costly regarding traveling expenses. One sells an unfamiliar product, the other an identical product which is advertised regularly in the JOURNAL.

Salesman No. 1 has to devote an excess of time to overcoming the lack of knowledge concerning his product, and naturally is limited to a materially small number of calls. Salesman No. 2, as a representative of an 'acquaintance,' gets around to considerably more doctors per day—reaching many more sales possibilities and running less danger of killing sales through the annoyance of taking up too much of a busy man's time.

Which of the houses represented, then, do you reason can logically sell at a smaller margin of profit—a saving to you—or can afford to use better and costlier materials in its product—an advantage to you?

The answer is obvious. Practically everyone today knows that an 'advertiser' meets less sales resistance and because of resulting sales volume can sell for less, or give a better product for the same money.

Why bring it up then? Merely to remind that it is "pocketbook wisdom" and sensible to buy the products or services you find advertised in these pages.

for Prophylaxis and Treatment
of the "common cold" -

CATARRHALIS COMBINED VACCINE or CATARRHALIS-INFLUENZA VACCINE *Lederle*

LEDERLE LABORATORIES have combined in these two vaccines the bacteria which have been consistently enumerated as being associated with attacks of "the common cold"

CATARRHALIS COMBINED VACCINE *Lederle* has the following formula

	Millions per cc.
<i>Mic catarrhalis</i>	200
<i>B. Friedlander</i>	200
<i>Pneumococcus</i> (Types I, II and III)	200
<i>Streptococcus</i> (Hemolyticus and Viridans)	200
<i>Staphylococcus albus</i>	200
<i>Staphylococcus aureus</i>	200

CATARRHALIS-INFLUENZA VACCINE *Lederle* is sometimes preferred. It is identical with Catarrhalis Combined Vaccine *Lederle* but, in addition, has an equal number of H influenzae bacilli

**A better hearing aid made
to individual requirements**

The RADIOEAR

The Selex A Phone is a new scientific invention which is intended to enable the medical profession to render a further service where the impairment will not respond to treatment. An analysis with this instrument determines the characteristics that must be built into each individual hearing aid. This goes to the laboratory and the hearing aid—THE RADIOEAR—is built with the characteristics shown by the analysis.

The RADIOEAR is an acoustically balanced instrument with proved scientific principles made to the specific analysis of the degree of hearing impairment of each individual. A comfortable efficient and highly perfected hearing aid.

Adaptability

Every doctor sees a wide variety of patients whose reactions to an identical treatment differ as much as the patients themselves. To provide the doctor with a choice of medication most suitable for the individual case of constipation, Petrolagar is prepared in five types.

The variation of laxative potency of the five types of Petrolagar affords treatment adaptable to a wide range of cases of constipation.

Petrolagar Laboratories, Inc., 8134 McCormick Boulevard, Chicago, Illinois

Petrolagar is a palatable emulsion of pure liquid petrolatum, (65% by volume) and number One Silver White Kobo Agar-agar accepted by the Council on Pharmacy and Chemistry of The American Medical Association for the treatment of constipation.

VITAMINS IN CANNED FOODS

IV. VITAMIN B₁

• The story of vitamin B₁ is quite long and involved. Properly, it has been fully covered at some length in authoritative dissertations on the vitamins (1).

The original vitamin B of Eijkman and of Funk, while definitely possessed of antineuritic potency, is now known to be of a complex nature. Between 1919 and 1926, the vitamin B complex was resolved into vitamins B (B₁) and G (B₂). Subsequent work has indicated the existence of other vitamins in the complex, whose chemical natures or relations to human nutrition are not as yet clearly understood.

As a direct result of many researches on vitamin concentrates, the chemical identity of the crystalline antineuritic factor has recently been described as a derivative of 6 aminopyrimidine (2).

It has been known for many years that vitamin B₁ may be destroyed by heat. In the canning procedure, a number of heat treatments of food may be involved, especially in the thermal "processing" of the product to insure its preservation. In the "process", many foods are subjected to a heat treatment after sealing in the can, to destroy spoilage organisms which may be present on the raw material. In other cases, the food is filled into the cans at a sufficiently high temperature to obtain the same result. Therefore, the question of the

effect of the canning procedures on vitamin B₁ frequently arises.

The times and temperatures necessary for the processing of canned foods are governed by a number of factors, important among them being the pH of the food itself. Highly acid foods require only short heat processes at the temperature of hot or boiling water to destroy spoilage organisms. The so called "non acid" or "semi acid" products require higher temperatures—usually 240°F (116°C.).

As might be expected, acid foods have been found to suffer only a slight loss of vitamin B during canning (3).

The degree of retention of vitamin B₁ in the non acid foods is not as high as in the acid foods (4).

This is partly due to the heat treatments accorded them and possibly also to their low acidity, since the vitamin is more stable in acid media.

The facts in the case may be summarized briefly by the statement that commercially canned foods may be depended upon to supply vitamin B to extents consistent with the amounts of the vitamin originally present in the raw materials from which they were prepared. Because of their widespread use, canned foods contribute a notable amount of vitamin B₁ to the American dietary.

BENZEDRINE INHALER

A Volatile Vasoconstrictor

- The structure of the rhinological tract is so complicated that, when congestion is present, the whole of the affected area cannot easily be reached by a liquid vasoconstrictor
- On the other hand a volatile vasoconstrictor diffuses throughout the entire nasal cavity Benzedrine* is a vasoconstrictor combining VOLATILITY with a POTENCY greater than that of ephedrine
- To present these two properties of Benzedrine in the simplest and most convenient manner, the inhaler form was adopted—an aluminum tube with gas-tight screw caps, containing a cotton roll impregnated with Benzedrine
- Thus, though the word "inhaler" may suggest the outmoded aromatic inhalers of the past, actually this presentation of Benzedrine is logically dictated by the properties of the drug itself
- And Benzedrine Inhaler—effective, convenient and inexpensive—marks a distinct therapeutic advance in the symptomatic treatment of head colds, sinusitis, vasomotor rhinitis, hay fever and nasal congestion generally

milk

to help relieve certain dermatological conditions

Calcium therapy has been successfully employed in many types of skin disorders. Certain cases of urticaria have responded favorably to calcium medication. In itching dermatoses, calcium therapy has greatly ameliorated the itching and, in many cases, calcium treatments have resulted in complete relief.

Milk is one of the richest food sources of calcium. It has been shown that the lactose in milk greatly *increases* the absorption of calcium. (It is believed that this increased absorption is due to increased intestinal acidity through lactic acid fermentation.) Thus it would seem that milk is a practical means to increase the calcium intake, so helping to maintain the health of the skin. *The Bureau of Milk Publicity, Albany*

THE STATE OF NEW YORK

**WE TAKE
EVERY PRECAUTION
TO SAFEGUARD
DAIRYLEA MILK!**

Milk, as it comes from a healthy cow, is pure and wholesome. From that point on, the quality of the milk depends on what is kept out of it. Nature intended milk to pass directly from one creature to another. She made no provision against exposure to outside elements. That is why we, the 40,000 Dairylea farmers, use every possible safeguard—from farm to doorstep—in the production of Dairylea Milk.

Products At the farm, the milk is immediately filtered, cooled quickly, handled only in sterilized utensils, kept in a sanitary building or room used for milk only—and we maintain a staff of dairy experts to inspect our farms and herds. At our plants every can of milk is inspected before it is accepted. Laboratory tests of specimens are made daily.

These are protective measures which none of us, working *alone* or in a small group, could afford to provide—safeguards that make Dairylea Milk Products the kind you can always recommend to your patients.

Produced by

THE DAIRYMEN'S LEAGUE CO-OPERATIVE ASSOCIATION, INC

DAIRYLEA

Our Pledge: We, the farmers of the Dairymen's League, recognize a definite obligation to the public. Since milk is nature's most nearly perfect food, we pledge ourselves, in the production of Dairylea Milk Products, to do everything within our power to safeguard their purity and quality.

**THE MENOPAUSE SYMPTOMS, HORMONAL STATUS,
AND TREATMENT**ROBERT T FRANK, M D , MORRIS A GOLDBERGER, M D , and U J SALMON, M D ,
*New York City**From the Gynecological Service and Laboratories of the Mount Sinai Hospital*

The menopause has been a bugaboo to the laity as well as the profession for many generations. Women call it "the change of life" because in their opinion it entails a complete alteration in their physical and psychical being. They anticipate obesity and flabbiness, loss of sex allure, diminution of libido as well as all the signs of rapid aging.

Menstruation ceases with established menopause. After surgical removal of the ovaries or x-ray sterilization the onset of the amenorrhea is abrupt. In the physiological menopause it is frequently preceded by menstrual irregularity, with too frequent and too profuse bleeding, or by increasing intervals between menstruations until the menses finally cease entirely.

Symptoms

The most striking symptom of the menopause is amenorrhea. This is accompanied by a gradual involution of the internal and external genital tract. Locally a shrinkage of the labia minora, a diminution of the sebaceous and mucous secretion, and pallor of the external parts develops. The vaginal mucous membrane shows less of these gross effects than the vulva although there is some dryness, and in the nullipara, a distinctly noticeable shrinkage in the caliber of the vaginal canal. The cervix diminishes in size, the cervical secretion, unless infection is present, becomes scant. The uterine body is thinner, flabbier, and smaller in size. Intramural fibroids especially if of small size involute, frequently to such a degree

that they can no longer be felt. The tubes show the least changes, although on microscopic examination, involution is likewise noted. The ovaries are fibrous, firmer, and smaller. They may still contain follicles, the majority of which rarely reach beyond the early Graafian stage. Only in two instances have I seen full sized mature follicles years after the menopause. Corpora lutea are not found.

The local changes just enumerated may give rise to symptoms. Occasionally dyspareunia is complained of. This applies particularly to women who have never borne children. At the time of the menopause mild urinary symptoms, such as frequency and burning may appear, due to atrophy of the urethral meatus, the thin vestibular epithelium then being more sensitive to moistening by urine (burning, itching). Mild attacks of cystitis are not uncommon. Due to the loss of muscular tone, latent cystocele, rectocele, and prolapse may be more noticeable to the patient and may increase at this time. Spotting after intercourse, due to rupture of adhesions at the fornices or to superficial erosions (senile vaginitis) may cause undue alarm.

The majority of patients complain of neurovascular symptoms which are included under flashes and sweats. These flashes may be extremely frequent, thirty to fifty a day, accompanied by profuse sweats, which awaken the patient at night, and cause head colds and bronchitis. On the other hand, patients of more stable nervous constitution may have no flashes.

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 29, 1936*

or may have them of mild degree and at infrequent intervals. The experienced physician often can predict with some degree of certainty which patients may be expected to have severe symptoms and which are likely to pass through the "critical age" without discomfort. As a rule, the more apprehensive, the more nervous, and the more maladjusted the patient is before the menopause, the more severe the symptoms.

Patients of unstable psychical makeup

** Two patients two courses of treatment.

are greatly disturbed by the neurovascular symptoms, and in the form of a vicious circle, suffer increasingly from marked nervous manifestations—headaches, transient disturbances of vision, dizziness, fatigability, insomnia, instability of temper, evidenced by flareups, crying spells, and unreasonableness. These symptoms are merely exaggerations of the patient's former response and almost invariably are greatly benefited by humane explanation and reassurance.

Joint pains, commonly designated as arthritis (arthralgia) although there is no absolute proof of actual joint changes, are often noted. The shoulders, elbows,

fingers, and knees are the most frequent sites. Mobility is unaffected. Objective changes are rarely demonstrable. (Table I)

Obese, flaccid women may gain in weight around the menopause. This is usually due to their letup in physical activities as well as to overeating. Careful study of the basal metabolism, blood chemistry, etc. have not substantiated a cause for this increase in weight (Geist, Goldberger, Reiss, and Lande¹). The prompt loss of weight following careful and conscientious dieting likewise confirms the view that the obesity cannot be directly ascribed to the menopause. Thin, spare, and active women, on the other hand, do not change in their weight or general makeup.

Attempts to ascribe hypertension to the menopause, in my opinion, have not been convincing. Hypertension, when present, appears to be unaffected by the onset of the menopause, is unimproved by the treatment effective on the other symptoms, and is most common in the age group which is undergoing the "change of life."

Certain genital diseases are more frequent during the menopause. They include kraurositis vulvae, vulvar carcinoma, and corpus carcinoma, but as yet no direct relationship between the cessation of menstruation and these troubles can be demonstrated. In a large group of early menopause due to surgical castration, comprising hundreds of patients, vulvar and corporeal cancer have not been noted, but two cases of kraurositis have occurred.

The symptoms of the menopause may be summed up as local, neurovascular, and psychical. Their gravity varies according to the psychical and nervous makeup of a given individual, severe in the nervous and labile, less marked in the stolid and well-balanced. Sexual feeling and response is affected in the rarest of instances. Physical fitness, sex attractiveness, and general health are undisturbed in normal individuals, as the menopause does not in itself produce progeria.

Hormonal status

The menopause has been studied for a number of years in our laboratory. We were aware and had drawn attention^{2, 3}

to the fact that approximately half of the patients who are in the menopause still excrete estrogenic substances in their urine Zondek,⁴ Österreicher,⁵ Albright,⁶ and others have shown that in the menopause the gonadotropic factor circulating in the blood and excreted in the urine, is regularly increased. These well-authenticated observations have been the subject

twelfth day only. The same applies to the amount found in the urine excreted, 500 c.c. of urine proving negative except during this same time of the cycle (Chart I of normal woman).

In the series of menopause cases studied, regardless of their causation, gonadotropic hormone was found in increased amount in both the blood and

CHART I—GONADOTROPIC CYCLE IN THE BLOOD AND URINE OF A NORMAL MENSTRUATING WOMAN

Above the base line is shown the number of rat units of follicle stimulating and luteinizing gonadotropic factor per liter of blood.

Below the base line, the amount of gonadotropic factor excreted in the urine per day

of more detailed study by us during the past years

Gonadotropic Factor

(R. T. Frank-U. J. Salmon)

Our observations are based on a series of fifty-two cases of which eleven were physiological menopause, thirty-one surgical castrates, and ten x-ray castrates. Our previous studies⁷ have shown that in the normal, cyclical, menstruating woman, forty c.c. of blood contain an amount of gonadotropic hormone demonstrable by our methods⁸ between the ninth and

urine. The amounts far exceeded that obtained between the ninth and twelfth day of the cycle in normal women. This excessive and continuous secretion and excretion of the gonadotropic factors has been definitely shown to be due to the unopposed action of the prepuitary when ovarian function has been abolished.⁹ Many investigators have claimed that the gonadotropic secretion present after castration or the menopause, produces merely follicle stimulation in the test animals. Our investigations have shown that this belief is erroneous. By combining acid precipitation with extraction in alkaline

medium, it was noted that the luteinizing factor likewise is present in excess in the menopause. Thus what formerly was considered a typical pregnancy reaction in test animals can be regularly obtained with menopause blood and urine.¹⁰ There is no danger, however, of confusing these menopause reactions with pregnancy tests as the amount of menopause blood or

after onset of the physiologic climax.

As the gonadotropic hypersecretion and excretion is known to be due to the pre pituitary action, unopposed by ovarian control,⁹ it is evident that administration of estrogenic substance in proper dosage should modify the symptoms and discomforts of the menopause. This form of treatment was used on a purely empiric

CHART II—GONADOTROPIC FACTOR IN BLOOD AND URINE IN A CASE OF SPONTANEOUS MENOPAUSE

Above the base line the circles with dots show the amount of gonadotropic factor per liter of blood in rat units, as shown by weekly samples.

Below the base line is the total excretion per day of the gonadotropic factors in the urine.

Acuity of symptoms above base line, in continuous line.

Vaginal smears in broken line.

The time of treatment is indicated by black vertical arrows.

Following treatment, disappearance of symptoms.

Positive vaginal spreads and disappearance of gonadotropic factors from blood and urine after a lapse of twenty-five days, gradual return to pretreatment condition.

urine necessary to produce a full luteinization of the ovary of the test rat, is so greatly in excess of that of pregnancy that no error can occur (Chart II).

The excessive gonadotropic secretion and excretion referred to has been observed by us as early as twenty-four days after castration and as late as ten years

basis by clinicians for many years, but the preparations and dosage available were insufficient. Severinghaus¹¹ was really the first to use approximately adequate dosage. Our method of hormonal control has enabled us to study and evaluate objectively the effect of treatment during and after it was given.

In our series of fifty-two patients, thirty-three cases were subjected to treatment, while coincidentally in the majority the gonadotropic factor was studied in blood and urine. The estrogenic preparation employed was Progynon B, for the liberal and continuous supply of which we are greatly indebted to Dr Stragnell of the Schering Corporation. This form of estrogenic substance was chosen because its absorption is slow and apparently continuous. Although much larger dosage was occasionally used it was soon found that 24,000 R U, corresponding to 120,000 International Units of Progynon B, injected over a period of two weeks, promptly caused a disappearance of both luteinizing and follicle stimulating factors from the blood and urine. This change in hormonal conditions was regularly accompanied by disappearance of the flashes, sweats, headaches, and frequently of the joint symptoms complained of. Patients noted a feeling of increased vigor and well-being.

The duration of relief varied considerably. In a certain number of cases, relief persisted as long as ten to twelve weeks. In the majority of patients, a beginning return of symptoms was noted as soon as two or three weeks had elapsed. In every instance in the special cases studied, the return of symptoms was accompanied by the reappearance in excess of the gonadotropic reactions in the blood and urine.

Vaginal smears Papanicolaou and Schorr¹² noted that the vaginal spreads of human castrates showed distinctive changes. In the great majority, the vaginal spreads were found to be similar to those of the negative phase of the menstrual cycle. When adequate doses of estrogenic substances were injected, a positive or, as they called it, a copulative phase resulted. In considerable number of patients in our series, vaginal spreads were taken by the patients themselves and were examined in our laboratory by a modified staining method,¹³ somewhat simpler than that used by Papanicolaou and Schorr. It was found that while the majority of menopause patients, included in all the three groups, had negative spreads before treatment, a small number showed positive spreads continuously (Fig 1). Nevertheless, the difference between the positive spread of the

untreated and of the treated patient, is sufficiently distinctive to be of diagnostic value*.

As will be evident from the chart, there is an inverse relation between the excess of gonadotropic hormone and the vaginal spreads. Gonadotropic hormone in excess is accompanied by the presence of negative vaginal spreads in the majority of cases, during treatment spreads become strongly positive, gonadotropic factors negative, with the return of the excess of the gonadotropic hormone, the spreads again return to negative. As the technic of taking vaginal spreads as well as their interpretation is so simple, this may prove another method of controlling the efficacy of the therapy, available particularly to the practitioner.

Estrogenic factor

(Morris A. Goldberger)

In a number of previous publications^{2, 3} we mentioned that the estrogenic factor could be found in some cases years after the physiological menopause had developed. In our present study it was noted that considerable, and at times large quantities of estrogenic factor, occur in the blood and urine of surgical castrates. A normal, cyclical, menstruating woman shows at least 1 M U of estrogenic factor in forty cc of blood in the last week preceding menstruation.² Twice during the cycle, namely, approximately at the time of ovulation, as well as three or four days before menstruation takes place, large quantities of estrogenic factor are excreted in the urine, throughout a cycle the average menstruating normal female excreting a total of 1500 M U (Chart III).

The frequent occurrence of estrogenic factor in the blood and urine of casual specimens obtained from human castrates,¹⁴ led us to study two castrates over a continuous period. As the appended graphs show, the excretion of estrogenic factor is not inconsiderable. (Chart IV).

It also seemed of importance to determine whether the large quantities of estrogenic factor (Progynon B) injected for the treatment of menopause symptoms,

*Although some untreated patients show purely squamous epithelium (positive phase) the nuclei of these epithelial cells are distinctly larger than those found in the treated patients.

medium, it was noted that the luteinizing factor likewise is present in excess in the menopause. Thus what formerly was considered a typical pregnancy reaction in test animals can be regularly obtained with menopause blood and urine.¹⁰ There is no danger, however, of confusing these menopause reactions with pregnancy tests as the amount of menopause blood or

after onset of the physiologic climax.

As the gonadotropic hypersecretion and excretion is known to be due to the pre pituitary action, unopposed by ovarian control,⁹ it is evident that administration of estrogenic substance in proper dosage should modify the symptoms and discomforts of the menopause. This form of treatment was used on a purely empiric

CHART II—GONADOTROPIC FACTOR IN BLOOD AND URINE IN A CASE OF SPONTANEOUS MENOPAUSE

Above the base line the circles with dots show the amount of gonadotropic factor per liter of blood in rat units, as shown by weekly samples

Below the base line is the total excretion per day of the gonadotropic factors in the urine

Acuity of symptoms above base line, in continuous line.

Vaginal smears in broken line.

The time of treatment is indicated by black vertical arrows.

Following treatment, disappearance of symptoms

Positive vaginal spreads and disappearance of gonadotropic factors from blood and urine, after a lapse of twenty-five days, gradual return to pretreatment condition

urine necessary to produce a full luteinization of the ovary of the test rat, is so greatly in excess of that of pregnancy that no error can occur (Chart II)

The excessive gonadotropic secretion and excretion referred to has been observed by us as early as twenty-four days after castration and as late as ten years

basis by clinicians for many years, but the preparations and dosage available were insufficient. Severinghaus¹¹ was really the first to use approximately adequate dosage. Our method of hormonal control has enabled us to study and evaluate objectively the effect of treatment during and after it was given.

and fruit was taken, dehydrated, and extracted. It was found that this meal contained thirty-three M U and that consequently the average individual ingests from 75 to 100 M U of estrogenic substance daily. Whether this amount is sufficient to supply enough estrogenic substance to account for what is found in a castrate, is by no means certain.

It therefore behooves us to look for another source. As yet our studies have not lead to decisive results. Whether synthesis of cholesterol by the liver, a substance closely related to the estrogenic hormones, will be found as the source, must as yet remain an open question.

Treatment

Out of fifty-two patients, thirty-three received treatment for their symptoms. The severest symptoms were complained of by the x-ray castrates.

The treatment given in the majority of cases consisted of the intramuscular injections of Progyon Benzoate (dihydro-folliculin benzoate) in ampules supplied

CHART III

Normal, fertile, menstruating woman. Showing preputiary and female sex hormone blood cycle and estrogenic factor excretion in the urine.

CHART IV

Surgical castrate showing excretion of both gonadotropic and estrogenic factors. No blood examination is charted. This surgical castrate excreted not only luteinizing and follicle stimulating factor but 637 M U of estrogenic factor during a month, less than $\frac{1}{2}$ the amount that a normal menstruating woman would excrete. The source of the estrogenic factor is not determined.

NEGATIVE SMEARS

were entirely utilized or were excreted, at least in part. Chart V shows the large amounts which appeared in the urine during treatment

While it is readily understandable that small quantities of estrogenic factor might be retained and deposited in depots before castration, yet after the elapse of a certain time, this residuum should be exhausted by utilization or excretion. As up to the present, no other sources for the production of estrogenic factor, except the ovary and placenta have been discovered, the question naturally arises where the estrogenic factor found by us years after castration, comes from

One possible source for the ES was mentioned by one of us a number of years ago, namely the food supply¹⁵. As most vegetables and many other common food products are known to contain estrogenic factor, it seemed worthwhile to determine how much estrogenic activity was contained in an average meal. A sample lunch from the hospital menu, consisting of meat, bread, milk, butter, vegetables,

oil may cause subcutaneous and intramuscular indurations which in rare instances are followed by granulomatous masses which have been known to break down and suppurate

Recently, through the courtesy of the Schering Corporation, we have been able to use, in a few selected cases, tablets of Progyon with as much as 1,000 "active" RU. These tablets we understand are not yet on the market, will probably prove to be expensive, but if manufactured in quantity, may become available. This method of medication should prove of far greater value than the giving of estrogenic factor by injection as the patient can take them as indicated. Our hormonal control shows that they are efficacious.

Finally the question cannot be avoided as to whether constant medication with large dosage of estrogenic factor may not entail a risk of favoring the production of cancer, as many investigations¹⁶ have shown the close chemical and biological relation of estrogenic and carcinogenic substances. This danger appears largely theoretical for, during pregnancy for example, huge quantities of estrogenic substance are constantly circulating in the blood and excreted in the urine. Time alone will show whether this possible potential danger is valid.

Summary

A study of fifty-two cases in the menopause—eleven physiological, thirty-one surgical castrates, and ten x-ray castrates—is reported. Of these patients, nine had no or only minimal symptoms.

1 The main symptoms of the menopause, irrespective of its origin, are amenorrhea, local pelvic atrophies, and neurovascular disturbances. In addition arthralgias, fatigability, depression, palpitation and dizziness, headaches, and gastrointestinal disturbances are complained of by a number of patients. The

age of the patients, the duration of the menopause play no decisive role. On the other hand, the nervous makeup and constitution are of great importance. With few exceptions, nervous and neurasthenic patients have the most violent symptoms. Neither obesity, hypertension, nor diminution of libido can be ascribed to the menopause.

2 Hormonal studies show that cessation of ovarian function is followed by persistent over-secretion (and excretion) of both gonadotropic factors of the prepituitary. Our studies likewise show that injection of the estrogenic factor in proper dosage, temporarily overcomes the excessive prepituitary action with rapid disappearance of these factors from the blood and urine. In at least fifty per cent of cases after the menopause and including surgical castrates, considerable quantities of estrogenic factor circulate in the blood and are excreted in the urine. The source of the estrogenic factor after the removal of the ovaries has not as yet been determined although the ingested food probably accounts for at least some of the factor found. The patient's vaginal spreads also give valuable objective information as to the effect of therapy.

3 Thirty-three patients were treated, some repeatedly, by means of Progyon B. The dosage finally selected as most adequate proved to be 24,000 RU (120,000 International Units) 4,000 RU given at a time (2 ampules) on alternate days, intramuscularly. The relief experienced from a single course of treatments lasted from one to eight weeks, the average being three to four weeks. No permanent relief results.

4 It is anticipated that when tablets of estrogenic substance, to be taken by mouth, are generally available, oral therapy will prove to be the best form of treatment.

depression, headaches, palpitation, and dizziness, as well as some of the gastrointestinal symptoms complained of. In some patients the joint symptoms also were relieved.

The duration of relief varied considerably, the shortest period being approximately one week, the longest eight weeks, the average around three to four weeks. Following the treatment, the excess of gonadotropic factor disappears from the blood and urine within a few days, the vaginal smears becoming strongly positive. All of these controls slowly return to the pretreatment type in close relation

by the exhibition of large dosage of estrogenic factor. This medication reduces and regulates the unopposed and excessive action of gonadotropic factors of the prepituitary gland. The treatment entails certain disadvantages. It is costly, the relief is but temporary, at present hypodermic injections are required which entail frequent visits to the physician. A few patients suffer from skin symptoms (swelling, itching, pain) particularly if the injections are made subcutaneously instead of intramuscularly. Moreover, it should be remembered that long continued injections of

oil may cause subcutaneous and intramuscular indurations which in rare instances are followed by granulomatous masses which have been known to break down and suppurate

The treatment entails certain disadvantages. It is costly, the relief is but temporary, at present hypodermic injections are required which entail frequent visits to the physician. A few patients suffer from skin symptoms (swelling, itching, pain) particularly if the injections are made subcutaneously instead of intramuscularly. Moreover, it should be remembered that long continued injections of

sary The incision to open the bed for the graft should be made to the periosteum of the frontal bone, and it should be properly placed as to height, with a little arching (Fig 1 and 2) In case a fellow brow will not furnish a good graft, the occipital or temporal region of the scalp will furnish a rather good detached graft, which can be trimmed by the patient when the hairs get too long Such a graft is to be regarded not as first choice, but as a fairly good substitute for brow

For eyelashes a graft from the lower part of the brow can be used. The brow hairs are too far apart for good eyelashes and direction is not perfect, but they do rather well. Sometimes, with the graft

surface skin, it is not necessary that the razor graft contain only epithelium as in eye socket restoration So the graft need not be taken with the degree of skill that is called for when the surgeon sets out to get only epidermis with no true skin and with no defect Such a razor graft as Thiersch took, with a little connective tissue, is permissible This graft is never ideal for lid surface, but it will match the burned face better than true skin from another part of the body, such as the arm, thigh or abdomen

For a granulating area in the malar region, the grafts of Reverdin (pinch grafts) still have a place. A thick mat of new-formed tissue, such as may follow the

Fig 1 Transplantation of part of right brow to form left brow Outlining incisions in right brow Skin in left brow region has been incised to periosteum

Fig 2 Graft from right brow has been turned about and placed for left brow Fine silk sutures have been tied

from the lower part of the eyebrow, skin below the brow should be carried along for correction of a defect of an eyelid In some cases it is possible for the surgeon to rob one lid margin of part of its cilia to furnish hairs for another It may even be justifiable in some cases for the surgeon to shorten the palpebral fissures so that cilia can be furnished

In ectropion the need is for suitable skin, and a good bed for the reception of a graft results from proper dissection⁷ A detached flap of upper eyelid skin is easily the best, and usually such skin is available. Next best is skin from the cephaloauricular angle. Dissection of skin from the angle is easy, and the wound can be satisfactorily closed without undermining⁸ In some cases of very severe burns neither the upper eyelid skin nor the cephaloauricular angle skin is available in sufficient quantity For such rare cases epidermis will answer⁹ It is best taken from the outer aspect of the thigh, where the skin overlies the fascia lata For lid

destruction of cancer, makes a poor bed for a large graft, but if many little islands of skin are placed on the surface some of them will live and assist in the process of skin formation Considerable contraction occurs in the healing process, but it creates little deformity in the convex surface of the malar region The eyelids may be stretched longitudinally by cicatricial contraction, but the palpebral fissure can be shortened when the period of contraction is passed

For filling in depressions a number of vital structures have been used Those ordinarily adopted have been fat, muscle, bone, cartilage, and fascia Depressions about the orbit are very likely to be associated with massive scar tissue formation so that when the dissection is made to insert filling, the cavity wall is made up wholly, or in part, of new formed connective tissue Either muscle or fat, pedunculated or non-pedunculated, is liable to break down in such a cavity and undergo frank contraction so that a de-

SOURCES OF GRAFTS FOR PLASTIC SURGERY ABOUT THE EYES

JOHN M. WHEELER, M D, *New York City*

Wisdom in the choice of grafts is essential for best results in plastic surgery in the eye region. There is room for difference of opinion, but for me choice of material is rather well-formulated, and I should like to make suggestions out of experience.

When Reverdin¹ in 1869 reported that he had successfully grafted little pieces of skin on a granulating surface and that the grafts had lived, he made a valuable contribution to surgical science, and he placed before plastic surgeons a valuable idea, namely, that pedicles are not always necessary for the life of grafts. Then Ollier,² Thiersch,³ Wolfe,⁴ and others in quick succession demonstrated that grafts of epidermis, dermis, and other tissues could be successfully transplanted without pedicles. With authority Tagliacozzi⁵ had offered his dictum that in order to live a graft must have an attachment to nearby tissue, that it must have a pedicle. And in spite of repeated demonstrations of life and well-being of independent detached grafts, the presumption of value of pedicle attachment has persisted to the present time. Witness the idea that is offered to us by Esser,⁶ the renowned Dutch plastic surgeon who is practicing his art in the Principality of Monaco. He assumes value of a vascular attachment for a skin flap. Instead of dissecting up a pedicle of skin he dissects out an important artery for a pedicle and buries it under skin to carry nourishment to a skin flap. With the artery go veins, nerves, and lymphatics, surrounded only by loose protective tissue. His conception is interesting, but he is wrong, it seems to me, in assuming that a vascular pedicle is ordinarily necessary for the life of a graft, and he accepts a serious handicap in operative technic, and calls on himself for unnecessary dissection, and secondary operations, giving his patient unnecessary facial scars.

In the face of high authority to the contrary, I should advocate the use of detached grafts in preference to attached flaps, whenever it is feasible for the

surgeon to choose. In so doing the surgeon can select a graft best suited to its use and usually of such size and shape as are needed.

In a small proportion of cases pedicles are important. An example is found in coloboma of the eyelid, which calls for a skin flap with conjunctival lining and a broad pedicle. The flap with its lining is simply advanced from the malar and temporal regions to its new position.

A pedunculated flap is called for if a proper bed cannot be prepared to receive a skin graft. A good example is furnished by a deep wound below the eye, with bone injury near the orbital margin and with a quantity of scar tissue that has partially filled in the depression. Here only a thick pedunculated flap can be relied on.

Another condition that demands a skin flap with pedicle is an actual hole into the nasal cavity, where there is no bed to receive the graft. In this case the pedunculated flap should more than cover the hole, and it should carry with it a patch of epithelial lining, the right size to accurately fit into the hole.

When used, pedunculated grafts should be from neighboring parts. In my opinion true skin from distant parts, such as the arm, forearm, thigh, abdomen or chest is never best.

For restoration of a socket there surely is no need for a pedicle. A complete lining of epithelium without underlying connective tissue is required. For the purpose I should choose epidermis from the outer aspect of the thigh, without glands or hair follicles and without perforation.

For eyebrow restoration a graft from a fellow brow is best. If there is plenty of brow on one side a full-thickness graft can be excised a few mm wide and of sufficient length. The brow tissue above and below can be brought together with very little undermining, and very little injury. The graft is turned about and placed in its bed with the hairs slanting in the right direction. No pedicle is neces-

New York City, April 29, 1936*

from each cephalauricular angle supplies the new skin surface below the eyelid graft. These pieces of skin will readily adapt themselves to the needed shapes, and the outlines of the grafts shown in Fig 6 illustrate the changes in shape

which may be called for. Often deformities about the eyes need different sorts of procedures and a liberal supply of ingenuity is needed.

Discussion

DR. WEBB W WEEKS, *New York City*—It was my good fortune to serve under Dr Wheeler for a while at Fort McHenry after the war in 1919. It was there he thought out, planned, and devised the best methods for the repair of a great variety of deformities about the eye. The base for his future work and great success in plastic surgery was in a great measure laid.

You have here had a glimpse of what extreme patience and care, deliberately planned and dextrously executed work can accomplish. Quite naturally I have tried to closely follow his teachings. While in France I saw much of the French sliding flaps and the Italian pedicle grafts which seemed tolerably good at the time, especially where tissue loss in the area grafted was extensive. Yet the contrast was remarkable where a free graft was used as done at Fort McHenry. You occasionally see now a disfiguring case where for more or less superficial scars causing an ectropion a Wolfe-Krause graft is used from the arm or thigh.

The Ollier-Thiersch graft from the lid or back of the ear has always served well in the repair of lid deformities. One trick of Dr Wheeler's has done well in the repair of depressions in fractures of the malar and maxillary bones. The fascia over the masseter with fat was hinged back over the depression while a regular skin graft was placed over it.

The Ollier-Thiersch graft from the thigh usually includes lining a socket for an artificial eye and covering the walls of an exenterated orbit. Mucus membrane grafts from the lip and buccal surface of the cheek give good surfaces and heal well in excision of the posterior portion of the lid margin for trichiasis, for repairing a symblepharon or supplanting a dry, atrophic and irritating bulbar mucus membrane seen in trachoma and essential shrinking of the conjunctiva in pemphigus.

Dr Wheeler speaks of the Reverdin graft for the poorly nourished scars after treat-

ment for epitheliomas in the lid and adjacent cheek areas. This is a very helpful idea exemplified in a recent case on the Bellevue Hospital service where several sliding grafts gave only a partial repair in spite of free excision and incisions into the indurated area.

Scrotal grafts for ectropion of the lids have been used with good takes, texture, and color by Dr Hughes of the Infirmary staff.

DR. JOHN F GIPNER, *Rochester, N Y*—In most undertakings and especially in surgical procedures, the simplest methods are usually the best. To Dr Wheeler goes the credit for pioneering in and popularizing simple and effective surgical procedures for the plastic repair of defects of the orbit, lids, and brow.

During the period of my ophthalmological training I had considerable experience helping Dr W L Benedict perform pedicle graft lid plastics. Secondary operations were frequently necessary. In his search for better methods, Dr Benedict became one of the first to use detached grafts as advocated by Dr Wheeler. As a natural result of my early training, I have followed Dr Wheeler's technic in my own practice. His surgical procedures, his choice of grafts, and his reasoning justifying his ideas on the subject have always appealed to me as being eminently sound and right.

The technic for using a thin epithelial graft in the restoration of contracted socket was published by Dr Wheeler fourteen years ago. The important point to be remembered in cutting the graft is to take only the superficial layers of the skin of the outer thigh without any connective tissue, glands or hair follicles. When such a graft takes, the epithelium lining the socket is thin, pinkish-white in color, and free from offensive secretion and hairs which will be present if the graft is cut too thick.

For the correction of ectropion after thorough removal of all scar tissue, the use

Fig 3 Large pigmented mole below right eye Primary incisions for excision

Fig 4 Dissection of skin occupied by pigmented mole Graft from left upper eyelid outlined

pression is re-established Bone and cartilage, even if fitted accurately are liable to become poor fits as changes in the wall of the cavity take place These grafts are insecure and often annoying to patients The one tissue that I have found absolutely satisfactory is fascia lata If the cavity is carefully dissected so its limits are correct, the fascia lata filling can be made to do its exact duty The tissue is of such a low grade that it will exist in contact with any sort of tissue and it will remain indefinitely with very little change provided the wound over it is secure It is never annoying to patients after the healing process and it adapts itself to cavities of any shape.

Sometimes the surgeon does best to use more than one kind of skin for a surface about the eyes An example of the successful use of three grafts to cover a

rather large surface occasioned by the excision of a pigmented mole is illustrated in Figs 3, 4, 5, and 6 In this case skin for the right lower eyelid near the palpebral fissure is supplied by a graft from the left upper eyelid, and a graft

from each cephaloauricular angle supplies the new skin surface below the eyelid graft. These pieces of skin will readily adapt themselves to the needed shapes, and the outlines of the grafts shown in Fig 6 illustrate the changes in shape

which may be called for. Often deformities about the eyes need different sorts of procedures and a liberal supply of ingenuity is needed.

Discussion

DR. WEBB W WEEKS, *New York City*—It was my good fortune to serve under Dr Wheeler for a while at Fort McHenry after the war in 1919. It was there he thought out, planned, and devised the best methods for the repair of a great variety of deformities about the eye. The base for his future work and great success in plastic surgery was in a great measure laid.

You have here had a glimpse of what extreme patience and care, deliberately planned and dextrously executed work can accomplish. Quite naturally I have tried to closely follow his teachings. While in France I saw much of the French sliding flaps and the Italian pedicle grafts which seemed tolerably good at the time, especially where tissue loss in the area grafted was extensive. Yet the contrast was remarkable where a free graft was used as done at Fort McHenry. You occasionally see now a disfiguring case where for more or less superficial scars causing an ectropion a Wolfe-Krause graft is used from the arm or thigh.

The Ollier-Thiersch graft from the lid or back of the ear has always served well in the repair of lid deformities. One trick of Dr Wheeler's has done well in the repair of depressions in fractures of the malar and maxillary bones. The fascia over the masseter with fat was hinged back over the depression while a regular skin graft was placed over it.

The Ollier-Thiersch graft from the thigh usually includes lining a socket for an artificial eye and covering the walls of an exenterated orbit. Mucus membrane grafts from the lip and buccal surface of the cheek give good surfaces and heal well in excision of the posterior portion of the lid margin for trichiasis, for repairing a symblepharon or supplanting a dry, atrophic and irritating bulbar mucus membrane seen in trachoma and essential shrinking of the conjunctiva in pemphigus.

Dr Wheeler speaks of the Reverdin graft for the poorly nourished scars after treat-

ment for epitheliomas in the lid and adjacent cheek areas. This is a very helpful idea exemplified in a recent case on the Bellevue Hospital service where several sliding grafts gave only a partial repair in spite of free excision and incisions into the indurated area.

Scrotal grafts for ectropion of the lids have been used with good takes, texture, and color by Dr Hughes of the Infirmary staff.

DR. JOHN F GIPNER, *Rochester, N Y*—In most undertakings and especially in surgical procedures, the simplest methods are usually the best. To Dr Wheeler goes the credit for pioneering in and popularizing simple and effective surgical procedures for the plastic repair of defects of the orbit, lids, and brow.

During the period of my ophthalmological training I had considerable experience helping Dr W L Benedict perform pedicle graft lid plastics. Secondary operations were frequently necessary. In his search for better methods, Dr Benedict became one of the first to use detached grafts as advocated by Dr Wheeler. As a natural result of my early training, I have followed Dr Wheeler's technic in my own practice. His surgical procedures, his choice of grafts, and his reasoning justifying his ideas on the subject have always appealed to me as being eminently sound and right.

The technic for using a thin epithelial graft in the restoration of contracted socket was published by Dr Wheeler fourteen years ago. The important point to be remembered in cutting the graft is to take only the superficial layers of the skin of the outer thigh without any connective tissue, glands or hair follicles. When such a graft takes, the epithelium lining the socket is thin, pinkish-white in color, and free from offensive secretion and hairs which will be present if the graft is cut too thick.

For the correction of ectropion, after thorough removal of all scar tissue, the use

Fig 3 Large pigmented mole below right eye Primary incisions for excision

Fig 4 Dissection of skin occupied by pigmented mole Graft from left upper eyelid outlined

pression is re-established Bone and cartilage, even if fitted accurately are liable to become poor fits, as changes in the wall of the cavity take place These grafts are insecure and often annoying to patients The one tissue that I have found absolutely satisfactory is fascia lata If the cavity is carefully dissected so its limits are correct, the fascia lata filling can be made to do its exact duty The tissue is of such a low grade that it will exist in contact with any sort of tissue and it will remain indefinitely with very little change, provided the wound over it is secure It is never annoying to patients after the healing process and it adapts itself to cavities of any shape

Sometimes the surgeon does best to use more than one kind of skin for a surface about the eyes An example of the successful use of three grafts to cover a

rather large surface occasioned by the excision of a pigmented mole is illustrated in Figs 3, 4, 5, and 6 In this case skin for the right lower eyelid near the palpebral fissure is supplied by a graft from the left upper eyelid, and a graft

Fig 6 Sutures have been tied to hold denuded areas on lid margins in apposition to form two intermarginal adhesions for the support of the lower eyelid Detached grafts have been placed to cover areas formerly occupied by pigmented mole

from each cephaloauricular angle supplies the new skin surface below the eyelid graft. These pieces of skin will readily adapt themselves to the needed shapes, and the outlines of the grafts shown in Fig 6 illustrate the changes in shape

which may be called for. Often deformities about the eyes need different sorts of procedures and a liberal supply of ingenuity is needed.

Discussion

DR. WEBB W WEEKS, *New York City*—It was my good fortune to serve under Dr Wheeler for a while at Fort McHenry after the war in 1919. It was there he thought out, planned, and devised the best methods for the repair of a great variety of deformities about the eye. The base for his future work and great success in plastic surgery was in a great measure laid.

You have here had a glimpse of what extreme patience and care, deliberately planned and dextrously executed work can accomplish. Quite naturally I have tried to closely follow his teachings. While in France I saw much of the French sliding flaps and the Italian pedicle grafts which seemed tolerably good at the time, especially where tissue loss in the area grafted was extensive. Yet the contrast was remarkable where a free graft was used as done at Fort McHenry. You occasionally see now a disfiguring case where for more or less superficial scars causing an ectropion a Wolfe-Krause graft is used from the arm or thigh.

The Ollier-Thiersch graft from the lid or back of the ear has always served well in the repair of lid deformities. One trick of Dr Wheeler's has done well in the repair of depressions in fractures of the malar and maxillary bones. The fascia over the masseter with fat was hinged back over the depression while a regular skin graft was placed over it.

The Ollier-Thiersch graft from the thigh usually includes lining a socket for an artificial eye and covering the walls of an exenterated orbit. Mucus membrane grafts from the lip and buccal surface of the cheek give good surfaces and heal well in excision of the posterior portion of the lid margin for trichiasis, for repairing a symblepharon or supplanting a dry, atrophic and irritating bulbar mucus membrane seen in trachoma and essential shrinking of the conjunctiva in pemphigus.

Dr Wheeler speaks of the Reverdin graft for the poorly nourished scars after treat-

ment for epitheliomas in the lid and adjacent cheek areas. This is a very helpful idea exemplified in a recent case on the Bellevue Hospital service where several sliding grafts gave only a partial repair in spite of free excision and incisions into the indurated area.

Scrotal grafts for ectropion of the lids have been used with good takes, texture, and color by Dr Hughes of the Infirmary staff.

DR. JOHN F GIPNER, *Rochester, N Y*—In most undertakings and especially in surgical procedures, the simplest methods are usually the best. To Dr Wheeler goes the credit for pioneering in and popularizing simple and effective surgical procedures for the plastic repair of defects of the orbit, lids, and brow.

During the period of my ophthalmological training I had considerable experience helping Dr W L Benedict perform pedicle graft lid plastics. Secondary operations were frequently necessary. In his search for better methods, Dr Benedict became one of the first to use detached grafts as advocated by Dr Wheeler. As a natural result of my early training, I have followed Dr Wheeler's technic in my own practice. His surgical procedures, his choice of grafts, and his reasoning justifying his ideas on the subject have always appealed to me as being eminently sound and right.

The technic for using a thin epithelial graft in the restoration of contracted socket was published by Dr Wheeler fourteen years ago. The important point to be remembered in cutting the graft is to take only the superficial layers of the skin of the outer thigh without any connective tissue, glands or hair follicles. When such a graft takes, the epithelium lining the socket is thin, pinkish-white in color, and free from offensive secretion and hairs which will be present if the graft is cut too thick.

For the correction of ectropion after thorough removal of all scar tissue, the use

of a full thickness, detached graft from an upper lid gives the best result.

Most of these grafts are successful. However, should the graft fail to take, one can use skin from the other upper lid or skin from the cephaloauricular angle. If this should be impossible, epidermis from the thigh can be used. Even after repeated failures, the loss of a full thickness graft or a Tiersch graft is never as troublesome as the loss of a pedicle graft. The following case illustrates this point.

On March 5, 1935, I operated a woman who had a large contracted scar of the left upper lid and brow resulting from a gasoline burn. The cornea was ulcerated from exposure to the air due to the fact that the lid was pulled up off the eyeball and was at no time in contact with the globe. After uniting the lids and dissecting out the scar tissue, a full thickness graft from the right upper lid was emplaced. Eight

days after the operation the graft was healthy and the result seemed satisfactory.

This woman was subject to attacks of dementia and had on several occasions been confined to a State Hospital. During a spell of dementia she completely destroyed the graft by clawing out most of the central portion with her fingernails. As healing progressed, more scar tissue developed so that within four months time the upper lid was again retracted upward and off the eyeball. On October 5, a second operation was performed using a Tiersch graft from the left thigh and the result was satisfactory.

Had the first repair been made with a pedicle graft, the problem of secondary repair would have been difficult. By using Dr. Wheeler's method, as long as suitable skin can be found on the patient, one may be confident that an ultimate correction will be secured, even though unforeseen reverses are encountered.

WHY APPENDICITIS FATALITIES ARE FALLING

The rising tide of deaths from appendicitis has finally been stemmed, notes the *Statistical Bulletin* of the Metropolitan Life Insurance Company. In the past five years the standardized death rate from this cause among Metropolitan Industrial policyholders, ages 1 to 74, has dropped steadily from 14.3 per 100,000 in 1931, to 11.5 in 1935, a decrease of twenty per cent. Among white male policyholders the rate last year, 13.5 per 100,000, was the lowest recorded in this group since 1919, particularly significant is the fact that white females in 1935 registered their lowest rate in a quarter of a century. Comparable data for the general population, available only to 1934, show the same general downward tendency.

Provisional figures for the first seven months of the current year point to the conclusion that the appendicitis death rate for the insured group as a whole will drop to even a lower level in 1936 than in the preceding year.

What factors have been at work to effect this recent improvement in mortality? This is a question of considerable current interest in the medical and public health fields, as is evidenced by the prominence given the subject in the periodical medical literature and at the medical society meetings throughout the country. Until very recently physicians have been stirred by the paradox of a decreasing operative mortality and a rising total appendicitis death rate. Whatever were the forces acting to raise the death rate for at least two decades beginning with 1911, it appears that now the trend of the mortality from this disease is definitely downward.

The lessened toll of deaths from ap-

pendicitis in recent years may be attributed in part to the widespread educational campaign conducted through the cooperation of public health officials, medical associations, insurance companies, retail druggists, school officials, and civic organizations. The educational attack against the excessive mortality from the disease has been centered on two factors which, obviously, were responsible for many deaths. The use of laxatives in the presence of abdominal pain, and the delay in hospitalization. The excellent statistical studies made by the health authorities in Philadelphia showed that, in recent years, only one in sixty-four of the appendicitis patients who had not received laxatives died, of those who had received one laxative, one in eighteen died, and of those who received more than one, one in eleven died. Similarly, the mortality of cases admitted to the hospitals forty-eight to seventy-two hours after the onset of the attack was about three times that for cases admitted within twenty-four hours.

Certainly the medical profession has made its contribution to the recent reduction in the appendicitis death toll. Everywhere physicians and surgeons have been critically analyzing their experience, and these investigations have undoubtedly led to improved practices. From the current literature it is clear that the disease is being recognized more and more readily, that surgical skill and judgment have reached higher levels, especially in the treatment of spreading peritonitis, that the types of anesthesia being used are resulting in a more favorable experience, and that preoperative and post-operative care have been improved.

Symposium: Silicosis

PATHOLOGY OF THE PNEUMOCONIOSES

LEROY U GARDNER, M D , *Saranac Lake*

*From the Saranac Laboratory for the Study of Tuberculosis of the
Edward L Trudeau Foundation*

Pneumoconiosis is a *condition* in the lungs resulting from the inhalation of dust. Unless the dust causing it has specifically irritating properties this condition cannot be of clinical significance and it should not be called a disease. Only two industrial dusts are now known to cause symptomatic *disease*, these are silica and asbestos. Animal injection experiments indicate that these two substances can cause progressive fibrosis in various tissues but that the reaction to even excessive quantities of other dusts is negligible.

At the present time any discussion of disease-producing dusts is narrowed to silica and asbestos. To produce effects both must be inhaled every day in high concentrations over a period of years. After exposures of five to twenty years scar tissue forms that may interfere with function but this is often not sufficiently severe to disable the individual or even prevent him from performing his habitual work unless infection complicates the picture. Unfortunately the development of silicosis seems to predispose an individual to tuberculosis. This comes about either through the reactivation of a latent focus of pre-existing tuberculosis or it may be due to a new infection from the outside. Asbestosis may have the same effect but it is by no means proven that it is responsible. Fewer cases of asbestosis than die show a complicating tuberculosis than is true of silicosis.

The diagnosis of either silicosis or asbestosis depends upon a history of an adequate exposure to the specific type of dust, a physical examination, and the presence of characteristic changes in a roentgenogram of the chest. This communication has to deal primarily with the pathological reactions responsible for the shadows seen in the x-ray film. Regardless of the history of exposure a diagnosis of silicosis is not warranted until the film

reveals the presence of multiple small nodular shadows in the parenchyma of both lungs. The fibrous nodule is the pathognomic lesion of silicosis and without it no diagnosis is possible.

The various manifestations of simple silicosis and silicosis with infection have been fully discussed in a report by a committee, of which the writer was a member, published in the *U S Public Health Reports*, August 2, 1935. The following tabulation of the lesions and the shadows which they cast upon an x-ray film is taken from this report.

Simple silicosis

- 1 Discrete nodulation
- 2 Conglomerate disease associated with discrete nodulation

Silicosis with infection

The following manifestations of infection are present upon a background of discrete nodulation.

- 3 The primary complex of childhood tuberculosis
- 4 Localized foci of healed adult type of tuberculosis situated in the apex of other portions of the lung
- 5 Aspiration or bronchogenic tuberculosis, either productive or exudated in type
- 6 Miliary tuberculosis
- 7 Perinodular tuberculosis
- 8 Chronic silico-tuberculosis

Insufficient exposures to silica may cause a certain amount of exaggeration of the linear shadows cast by the vascular tree, and enlargement of the tracheo-bronchial lymph nodes. These changes are not specific for silica, they may be produced by inhaling other dusts by infection and by heart disease. Since all of these factors may be operative upon the person who works in a silica industry, one is not justified in attributing the roentgenologic appearances to the silica. Let it be emphasized that without nodula-

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 28, 1936*

tion a diagnosis of silicosis is unwarranted at the present time

Simple discrete nodulation is not disabling and does not cause subjective symptoms. Where conglomerate disease complicates nodulation there is usually dyspnea which may be so severe as to incapacitate for work. Infection, if inactive, has the same effect. If active, the infection obviously requires treatment and the man should be hospitalized for his own good and the protection of his fellow-workmen. A person with simple discrete nodulation may be allowed to continue his regular work as he is not incapacitated and particularly as industries enlightened enough to discover such conditions in their employees are taking steps to eliminate their dust hazards.

The pathological changes responsible for the roentgenological appearances just described develop in the following manner:

1 *Exaggerated linear markings*, as already mentioned, are not specific for silicosis; they may be produced by many forms of irritation. The shadows are cast by heavy accumulations of pigment and slight chronic inflammatory reaction in the areolar coats of the pulmonary blood vessels. This reaction develops primarily in and about the lymphatic trunks that course through the walls of these vessels. Similar changes occur about the lymphatics of the bronchi and those that traverse the connective tissue septa between pulmonary lobules. When caused by silica, such inflammation tends to be heavier and more fibrous in character, and associated with it there are minute nodules of fibrosis in the intrapulmonary and tracheobronchial lymphoid tissues. When such reaction has progressed sufficiently it may be manifested in the roentgenogram as beading along the trunks and a widened mediastinal shadow. The effect of such changes is to compress and partially obliterate lymphatic channels. This interferes with free elimination of inhaled foreign bodies but it has no effect upon respiratory function. In a group of iron miners well-marked linear exaggeration was present after an average exposure of eighteen years. Men who had worked in rock dust (silica) showed the same amount of reaction after an average exposure of 11 years. A perilymphatic reaction caused by silica does not progress to parenchymatous nodulation without further exposure to dust. Since this change may be produced by so many forms of irritation, it is often impossible to

determine its origin. After autopsy, microscopic sections may reveal characteristic silica reactions but frequently even such evidence is difficult to evaluate.

2 *Simple discrete nodulation*, uniformly distributed throughout both lungs, is the pathognomic manifestation of silicosis. It is produced by nodules of laminated hyaline fibrous tissue thickly scattered through the parenchyma of the lung. Such lesions develop in lungs whose lymphatic drainage system has been damaged by previous perilymphatic changes. The phagocytes are no longer able to carry inhaled dust particles out of the air spaces so they deposit the silica in masses situated either in peripheral lymphoid areas or in the alveolar septa. The focal concentrations of silica stimulate a proliferation of connective tissue cells in their vicinity and a nodule slowly evolves. The size and character of these lesions depend upon the number and size of the silica particles that they contain. An excessive quantity of very small particles causes tissue necrosis surrounded by only a thin zone of fibrosis. Subsequently calcification and even ossification may replace the necrotic portions. Fewer and larger silica particles cause a less severe injury, which is countered by proliferative reaction. The resultant nodule is almost entirely composed of thick hyaline connective tissue fibers. If the inhaled dust in addition to silica, contains considerable of other substances like coal or iron, the structure of the nodule is further modified. The central zone may be specifically pigmented black or red and about it is a peripheral zone of heavily pigmented cellular connective tissue that sends prolongations into adjacent connective tissues. The section of the nodule is no longer circular but it has a stellate contour with a central core of dense fibrosis.

The reaction to focal collections of silica is progressive in the strict sense, but the amount of new reaction after discontinuing the dust exposure is limited and confined to the immediate surface of nodules already formed. Thus, nodules that might measure two mm in diameter after five years exposure to high concentrations of pure silica dust could enlarge to four mm after several years residence in a normal atmosphere, but very few new nodules would develop. A person whose lungs are involved with simple discrete nodulation is usually ignorant of his condition because there is still a large factor of safety in the remaining portions of the organs. Refined physiological technics may reveal impairment, but this is not sufficiently pronounced to interfere with the performance of habitual work.

In the group of miners already mentioned

roentgenographic manifestations of nodulation were first detectable after average exposures of 29 years in pure rock dust, but these same individuals had also averaged 229 years in ore dust. In advanced (third) stage nodulation the average exposure to rock dust was 59 years together with 287 years in ore. None of the men were working only in rock so that the rate of reaction to silica alone could not be determined.

3 *Massive conglomerate nodulation* is not so well-understood. It is manifested by extensive areas of fibrosis, often bilateral, that do not change materially over a period of years. Usually such lesions are superimposed upon a background of generalized nodulation but in some cases the isolated nodules are lacking or very few in number. Compensatory emphysema regularly complicates the picture. Conglomerate fibrosis seems to be particularly common among granite cutters and anthracite coal miners. Whether the non-silicious components of the dusts that these men inhale play a part in causing such reaction is not yet clear. It may occur in the silicosis of other industries.

It was formerly believed that conglomerate nodulation develops as a result of gradual increase in the number and size of the nodules so that they fuse together. This explanation is hardly adequate for a number of reasons. Dust inhaled into the normal lung is uniformly distributed and the nodules that form in response to it are neither larger, more numerous nor more rapid in evolution in one part of the organ than the other. Accidental confluence should theoretically be manifested everywhere but such is not the case. It occurs in isolated areas with no particular site of predilection. Therefore previous injury has been postulated to explain the excessive reaction that occurs in certain regions. Histological examination of tissues from terminal cases supports this hypothesis. The silicotic nodules are not merely crowded together so that the intervening air spaces are obliterated, they are still scattered but between them is a matrix of diffuse fibrous tissue that has replaced the normal pulmonary tissue. No evidence of active inflammation can be detected although here and there the arrangement of the fibrous tissue suggests that an organized pneumonia was responsible. If this is the explanation, one would expect to find a history of respiratory illness in some of these cases. Such is not generally the case and the hypothesis therefore becomes less tenable. But it still remains the most likely possibility. Subjective symptoms of pulmonary infections in the silicotic are generally trivial and even active tuberculosis can continue to progress for a long time before

its victim becomes aware of his condition. It therefore seems likely that milder infections would be entirely overlooked.

The frequency of slight pulmonary inflammations in the general population has only been appreciated since serial roentgenograms were commonly used in diagnosis. Even an insignificant patch of pneumonic reaction in a person exposed to high concentrations of silica dust should set up conditions that favor the local retention of inhaled particles. Silica, thus concentrated, will accentuate a pre-existing inflammatory process, prevent its resolution, and encourage organization. Such a sequence establishes a vicious circle for more dust will continue to be entrapped as the intensity of the inflammation increases. Final conclusions on the etiology of massive conglomerate fibrosis must await prolonged serial roentgenological study on a considerable group of persons and the evidence from more postmortem examinations.

For the present it suffices that this type of reaction be recognized as a manifestation of simple silicosis and that it be differentiated from a complicating, active infectious lesion. The diagnosis is not too difficult if conglomerate fibrosis is associated with generalized discrete nodulation, an effect probably produced by local injury developing subsequent to the formation of the nodules. But when extensive inflammation occurs before nodules have formed, most of the dust is apparently retained in such areas and little is deposited in other parts of the lung. Under such circumstances the only manifestation of silicosis may be massive areas of fibrosis with perhaps a few discrete nodules at their periphery. The diagnosis then becomes a problem that may require considerable study.

The clinical significance of conglomerate fibrosis is much greater than that of discrete nodulation. Either of itself or because of the associated emphysema it causes dyspnea and a definite limitation of working capacity. Cardiac hypertrophy complicating silicosis frequently occurs in cases with conglomerate fibrosis although a casual relationship between the two conditions has not yet been proved.

The manifestations of tuberculosis in silicosis may closely simulate those encountered in otherwise normal persons except for the fact that they occur upon a background of generalized nodulation. Such, for example, are the primary complex, the scars of healed apical tuberculosis, the bronchogenic aspirations, and miliary tuberculosis. Special types peculiar to silicosis are perimodular infection and silico-tuberculosis.

tion a diagnosis of silicosis is unwarranted at the present time

Simple discrete nodulation is not disabling and does not cause subjective symptoms. Where conglomerate disease complicates nodulation there is usually dyspnea which may be so severe as to incapacitate for work. Infection, if inactive, has the same effect. The diagnosis is not too difficult if conglomerate fibrosis is associated with generalized discrete nodulation, an effect probably produced by local injury developing subsequent to the formation of the nodules. But when extensive inflammation occurs before nodules have formed, most of the dust is apparently retained in such areas and little is deposited in other parts of the lung. Under such circumstances the only manifestation of silicosis may be massive areas of fibrosis with perhaps a few discrete nodules at their periphery. The diagnosis then becomes a problem that may require considerable study.

The clinical significance of conglomerate fibrosis is much greater than that of discrete nodulation. Either of itself or because of the associated emphysema it causes dyspnea and a definite limitation of working capacity. Cardiac hypertrophy complicating silicosis frequently occurs in cases with conglomerate fibrosis although a casual relationship between the two conditions has not yet been proved.

The manifestations of tuberculosis in silicosis may closely simulate those encountered in otherwise normal persons except for the fact that they occur upon a background of generalized nodulation. Such, for example, are the primary complex, the scars of healed apical tuberculosis, the bronchogenic aspirations, and miliary tuberculosis. Special types peculiar to silicosis are perinodular infection and silico-tuberculosis.

4 *The primary complex* of childhood infection is rarely influenced by the inhalation of silica as the lesions are usually healed and sterile by the time men are exposed to silica under modern industrial conditions. Experimentally, and very occasionally in human beings, such lesions can be reactivated and caused to spread by the silica that accumulates about them.

5 *Healed apical scars* of adult type reinfection tuberculosis may also be sterile at the time a man begins work in a silica hazard but the younger he is the more likely they are to harbor living organisms. Brown and Sampson¹ have demonstrated that in most persons such scars develop before the age of twenty-five. Presumably the same is true in silicotic subjects although this remains to be demonstrated. Such lesions, if they are potentially active, involve a certain amount of risk as inhaled silica may ultimately bring about reactivation and gradual spread of the infection. Usually it takes years for this to occur and the tuberculosis only becomes manifest in the later age periods (forty-five to fifty-four). The resultant disease is usually very chronic and the spread most often occurs by local extension. Since the subject is usually still at work silica dust tends to accumulate in the area of tuberculous inflammation. The combined action of tubercle bacilli and silica produce a chronic form of disease known as silico-tuberculosis.

6 *Silico-tuberculosis*. The cellular reaction is pre-eminently proliferative in character, a granulation tissue that is constantly becoming fibrous under the influence of the silica. Exudation is largely confined to the bronchi and little caseation develops. Cavities may ultimately form but when they do, they are usually terminal events, such reaction beginning in the top of the lung creeps slowly downward. It, like the conglomerate lesions of simple silicosis, causes dyspnea, but symptoms of intoxication and tubercle bacilli in the sputum often fail to appear for years. If such a lesion is situated in the apex of the lung its position is strongly suggestive of tuberculous origin. When a similar condition is found in other parts of the lung it will require study to differentiate it from *simple conglomerate fibrosis*. Unfortunately for the diagnostician, basal tuberculosis is much more common in the silicotic than in other subjects so that he is faced with this problem not infrequently. The behavior of the lesion in serial examinations, the clinical findings, and the sputum must all be carefully considered in arriving at a diagnosis. The origin of a basal silico-tuberculosis is not easy to determine particularly when it is observed for the first time in a well-advanced stage. Some of the cases

may have developed from reactivated primary foci of infection but in most instances one is forced to postulate an exogenous reinfection acquired during industrial life.

7 *Aspiration or bronchogenic tuberculosis* is relatively uncommon in the silicotic subject because cavities only form in the late stages of the disease. When it does occur the resultant reaction in new areas of the lung are more apt to be proliferative in type, although caseous bronchopneumomas are sometimes encountered.

8 *Miliary tuberculosis* is a terminal event that requires little comment. The writer has seen it most frequently in granite cutters for some unexplained reason.

9 The term *perinodular tuberculosis* has been included in the classification to describe an appearance seen in roentgenograms. The silicotic nodules appear to have fluffed out like kernels of corn that have popped. No case of this kind has come to autopsy before the infection has spread so far that this peculiar appearance was completely obscured. However, the effect can be reproduced in animals by intravenous injection of tubercle bacilli after the development of a generalized nodular silicosis. The organisms seem to localize in and upon the surface of the nodules followed by the development of a zone of tuberculous reaction about each lesion. Whether hematogenous infection is responsible for such reaction in human cases is not yet clear.

The lesions of asbestosis can not be included in a catalogue of the changes found in silicosis. Reaction to asbestos develops in a different manner. The dust particles being fibrous are not successfully removed from the air spaces by motile phagocytes. Instead they tend to remain where they originally lodge in the fine terminal bronchioles. In the walls of these structures they stimulate proliferation of connective tissue cells. As more dust is inhaled the fibrosis creeps toward the periphery. Ultimately the terminal air spaces are involved and large areas of the pulmonary parenchyma are obliterated by scar tissue. Fine emphysema is usually associated with the fibrosis. There are no nodules because the phagocytes do not concentrate the dust in focal areas. The lymphatic system does not participate in the reaction. Susceptibility to tuberculosis is probably somewhat increased but not to the same extent as in silicosis. Examination of large groups of asbestos workers in this country has failed to demonstrate an excessive incidence of

active infection Among fatal cases that were autopsied in England, Merewether² reports the incidence of tuberculosis as thirty-eight per cent, while in the silicotic group it was fifty-nine per cent. In experimental animals exposed to asbestos dust, infection with attenuated tubercle bacilli produces a temporary progression of the tuberculosis followed by healing with deforming fibrosis. In silicotic animals the same type of infection causes a chronic silico-tuberculosis that eventually terminates in death. Apparently infection in the case of asbestosis is important because it accentuates the fibrosis initiated by the inhaled dust.

The present experience with cases of silicosis has permitted certain generalizations to guide the physician in his treatment. These concepts may have to be modified later but they represent the consensus of informed opinion in this country today.

Summary

1 Accentuation of the linear markings in a pulmonary roentgenogram does not constitute a basis for a diagnosis of silicosis. The change is non-specific and even in persons with a history of prolonged exposure to silica, it may be due to other causes.

2 Simple silicosis is manifested by nodulation uniformly distributed throughout both lungs. This condition does not incapacitate for work, it does not produce symptoms. It is progressive to only a limited degree. A person with this type of reaction may continue in his regular employment although recognition of his condition presupposes that every effort will be made to reduce the dust in which he works to a minimum concentration. He should be subjected to roentgenographic examination once a year to be certain that no infection is developing in his lungs.

3 Simple silicosis may also be manifested by massive areas of conglomerate fibrosis usually associated with generalized discrete nodulation. Such cases usually have dyspnea and are definitely limited in their capacity to work. They should be given lighter jobs commensurate with their abilities. To discharge them will only make a hypochondriac and a possible litigant.

4 Uncomplicated silicosis is not fatal. The predisposition to infection, in most instances tuberculosis, constitutes the grave danger from this condition.

No person with open tuberculosis should be permitted to work in an industry where silica dust is created. An old employee with closed silico-tuberculosis that does not incapacitate him may be allowed to do light work in departments where no dust is generated. Sanatorium treatment may be tried but it is often ineffective. A young employee with silico-tuberculosis should be given the benefit of sanatorium treatment.

5 Persons over forty with roentgenographic evidence of well-healed adult type tuberculosis can be safely employed in an industry with a silica hazard. Their only danger lies in the development of a massive conglomerate type of fibrosis. But it is assumed that an industry that is having preemployment examinations is cognizant of the hazard and is making every effort to reduce the dust concentrations in its plants.

6 The younger the individual with x-ray evidence of healed adult type tuberculosis, the less safely can he be exposed to silica dust.

7 Roentgenographic evidence of a healed primary complex in a person over sixteen years of age does not constitute grounds for disbaring him from exposure to silica.

The silicosis problem can be solved by preemployment examinations of all applicants for work to select those who may safely expose themselves to silica dust, by periodic examinations of persons already employed to detect the development of infection that is amenable to treatment in its early stages, and by engineering methods to prevent or at least reduce the formation of dust.

8 Such a program involves intelligent cooperation between employer and employee with full knowledge of both parties of the dangers and the methods for the elimination. The responsibilities of the industrial physician are obvious. He must be competent in diagnosis and must zealously guard the interests of both employer and employee.

DIFFERENTIAL DIAGNOSIS OF SILICOSIS FROM OTHER PULMONARY DISEASES

GEORGE G. ORNSTEIN, M.D., F.A.C.P., *New York City*

From the Department of Tuberculosis, Metropolitan and Sea View Hospitals

The differential diagnosis of silicosis from other pulmonary diseases is not as simple as one is led to believe. This is perhaps most easily demonstrated by discussing a group of patients indexed as having silicosis with pulmonary tuberculosis. At the Metropolitan Hospital, since 1928, 110 cases were catalogued as having both silicosis and pulmonary tuberculosis. On closer analysis, however, fifty-one cases had to be discarded as having no silicosis. Of the remaining fifty-nine cases, 45 were admitted to the hospital with an admission diagnosis, not of silicosis or silico-tuberculosis, but of straight pulmonary tuberculosis. Of these fifty-nine, extensive hospital study showed that thirteen had no clinical tuberculosis at all, but far-advanced silicosis. When one stops to consider that these cases had filtered through the hands of experienced diagnosticians, the inconsistencies become even more amazing. This naturally leads to the question of reliability of vital statistics in general, as far as silicosis is concerned, especially where the final diagnosis is made by the local practitioner, away from the hospital service. This will be further discussed elsewhere.

It is interesting to note how infrequently the patients were aware of their occupational hazard, or their silicotic disease. It was the x-ray appearance in many instances which stimulated the resident and attending staff to be on the alert for pneumonokoniosis. There is a current tendency to look upon all bronchogenic dissemination of tuberculous pathology, especially where the size of the nodules is small, as potential cases of silicosis. This is especially true with x-ray staffs. Without history, in view of a diffuse mottling, a report may state—"pulmonary tuberculosis with silicosis." On investigation of the history of the patient, there is no statement of exposure to silica dust. On discharge or death of the patient, an ambitious clerk carefully indexing the various diagnoses, immedi-

ately adds the roentgenologist's impression of silicosis.

In a similar manner, physicians, without considering the industrial history of the patient, and being influenced by the roentgenogram, dictate into the follow-up record the diagnosis of silicosis.

With such errors made both by the x-ray department and the visiting staff, fifty-one out of 110 cases reported as having silicosis had to be discarded.

The diagnosis of silicosis should not be made unless there is a definite history of exposure to silica dust. It would be ideal to know the concentration of free silica, the duration of the exposure, the dust count, and size of the particles. Unfortunately, such data is most difficult to obtain even in this local area. We are to be guided by the fact that in dust containing twenty per cent free silica, the dust count being above 200,000,000 particles per cubic foot, and the particles chiefly under five microns in diameter, it would take an average of four to five years for the development of pulmonary silicosis. When the concentration of free silica in the dust increases, the time duration correspondingly is shortened. Cognizant of the above, we know that an individual shoveling soft coal can not develop pulmonary silicosis. Yet how frequently is such a diagnosis made. One should stress that where the jack hammer is used, there is the greatest concentration of dust.

Without a definite history of sufficient exposure both in regard to concentration and duration of exposure, one must be hesitant in making a diagnosis of silicosis. Recently I reviewed an interesting legal case. An overseer of a group of street excavators made claim for compensation because of a pulmonary tuberculosis complicating silicosis. There was no question in regard to the diagnosis of pulmonary tuberculosis. The difficulty arose with the diagnosis of the silicosis. There was bilateral upper lobe cavitation with a bronchogenic seeding down both lungs. The diffuse bilateral bronchogenic tuber-

culosis was interpreted by a group of physicians as silicosis. Of course, with a history of short duration of exposure, and very little chance for concentration as would occur in the open streets of New York City, the diagnosis of silicosis should have been discarded. Furthermore, in reviewing the serial x-rays, it was noted that the maximum intensity of the bronchogenic seeding was in the first x-rays taken. From then on, the serial x-rays revealed a slow resolution of the diseased areas. Resolution does not occur in silicotic nodules. The nodule in silicosis either remains stationary or progresses.

Another patient at the Sea View Hospital had a vague industrial history, and still a diagnosis of pneumonosis with pulmonary tuberculosis was made. A white male, age fifty-eight, stated that he had worked almost all his life chipping paint in the shipyards. He used an automatic chipping machine. He stated that there was considerable silica used in ship paint. The visiting physician also calculated that there should have been considerable iron dust. To the x-ray slip, a note of an industrial history had been added, and the following x-ray report was returned:

Diffuse acinous and nodular exudative and productive disease, irregularly distributed throughout the upper two-thirds of both lungs. The disease has a tendency to become confluent in areas. There is slight excavation in the left infraclavicular region.

The x-ray diagnosis was pulmonary tuberculosis superimposed on silicosis.

Were it not for an autopsy there would have been another case on record of silicotuberculosis. The disease was a progressive pulmonary tuberculosis which caused death in two months. There was no macroscopic or microscopic evidence of silicosis. Apparently, if silica is used in ship paint, there is not sufficient concentration to cause silicosis.

On the other hand, the history may be misleading. One is hesitant to suspect silicosis in the owner of a grocery store. An adult white male fifty-five years of age had a diffuse pulmonary fibrosis. The first diagnosis was a cirrhotic form of pulmonary tuberculosis, but in view of repeatedly negative sputa for tubercle

bacilli, in the presence of copious expectoration, the diagnosis of tuberculosis had to be discarded. Pulmonary syphilis was also given consideration. At first, he remembered no exposure to silica dust. He had never used a jack hammer or was employed in mining. Fortunately, he was asked if he had ever polished metal, and he then revealed a history of years of use of clay in the making of spark plugs which he then had to polish by grinding.

Wherever there is evidence of pulmonary fibrosis, one must write a detailed history of previous occupation.

Now, since silicosis has become compensable in New York State, employers, to rule out silicosis, have had all employees x-rayed. An adult male a clerk in charge of the payroll of a gang of rock-drillers, was also x-rayed. He never had been exposed to silica dust. An x-ray of his chest was interpreted as advanced silicosis, and he was told to look for another position. He did have spasms of coughing and expectoration, and became alarmed because of the diagnosis of silicosis. On examination it was found that he had fibrosis in both lower lungs secondary to nasal instillation of as much as an ounce of paraffin oil a day. His employer was contacted, and his position was restored to him.

Where there is sufficient occupational history, the x-ray becomes the most important examination for the diagnosis of pulmonary silicosis. Perhaps this must also be stated with reservations, for in the early stages of silicosis, the root and bronchial accentuation can be easily simulated by either bacterial infections or by other irritants. Just as in the last case paraffin irritation of the bronchi may also be a coincidental happening in a worker exposed to silica dust. In fact, because of nasal irritation, he may be more addicted to the use of nasal oils. In a similar manner, he may have either a sinus infection or a chronic nasopharyngitis with an infection of the lower bronchial tree, which could easily simulate the early stage of silicosis.

The first stage, as pointed out in the classification of Lanza and Childs in 1917,¹ has a bilateral increased density of root and bronchial markings. Small nodulation at the hilar areas or along the bronchi may be present. There is no dis-

tortion of the thoracic contents, and the diaphragms move freely

In the second stage, there is besides the above a symmetrical dissemination of small circumscribed dense areas. The distribution is usually in the lower part of the upper third of the lung, at about the level of the upper hilar region. In a later stage, the areas may increase in size. The domes of the diaphragms appear more accentuated.

The third stage is a further progression from the second stage. There is massing of the dense areas. Tracheal and mediastinal changes may occur, and in advanced progression tenting, displacement, and limited motion of the diaphragms may also occur.

If silicosis were only limited to the above stages, there would hardly be a discussion of differential diagnosis. There is, unfortunately, a more advanced stage of silicosis, and one in which there is great difficulty in ruling out tuberculosis. The confusion comes from the dense areas to which various investigators have used the term "infective silicosis." How confusing these shadows are, can only be illustrated by the fact that in most of the fifty-nine cases collected at the Metropolitan Hospital, a diagnosis of pulmonary tuberculosis was made, and the patients transferred without a suspicion of an occupational disease.

More interesting is the fact that in this group of fifty-nine patients thirteen were diagnosed as far-advanced pulmonary tuberculosis with sputa negative for tubercle bacilli. It is this type of case that causes so much confusion in regard to the association of tuberculosis and silicosis, and is usually labelled silico-tuberculosis. This group can not be classified as clinical tuberculosis, with sputum negative for tubercle bacilli, no more than we could label other patients with fibrotic tissue in the lung and with negative sputa as tuberculous. We have had autopsy material of this type of case at Sea View Hospital, where only silicosis was found, and there was no evidence of pulmonary tuberculosis. If the pathologist had found a number of small areas of healed tuberculosis in the silicotic infected area, would the finding of these areas warrant the addition of tuberculosis as a contributory cause of death? We can

now understand the confusion that has occurred in the listing of workers as silico-tuberculosis. It is my opinion that no clinical diagnosis of pulmonary tuberculosis should be made where there is copious expectoration and tubercle bacilli are absent. The literature abounds in the legend that bacilli are difficult to demonstrate even in advanced silico-tuberculosis. McFarland² explains the infrequency of cross-infection in the families of the granite workers on the basis of the infrequency of finding tubercle bacilli in the silico-tuberculous cases. Can we accept such explanations? In my opinion the absence of tubercle bacilli is more fact than legend. These workers have silicosis but no active pulmonary tuberculosis.

When thirteen of fifty-nine cases or twenty-two per cent can be incorrectly diagnosed by men trained in pulmonary disease as advanced pulmonary tuberculosis without suspecting an occupational disease, we can understand why, in areas of silica dust exposure, every death caused by silicosis is attributed to tuberculosis. How infrequently in these areas do we find a death certificate attributed to simple silicosis? Unfortunately, most studies of the relationship of tuberculosis to silicosis are based on studies of vital statistics. Such vital statistics are of little value. Jarvis,³ in a study of vital statistics in Washington County, Vt. over a period of twenty years up to 1921, states that there were eighty-five per cent tuberculous deaths among silicotic patients. McFarland² quotes Hoffman's figures of 1095.5 deaths per 100,000 in silicosis, compared with 94.6 per 100,000 in other males above the age of twenty. Should these reports form the basis of our knowledge of the association of tuberculosis and silicosis? Even Hoffman's figures, which suggest a very high death rate per 100,000, demonstrate that probably all cases of silicosis do not die of tuberculosis, as has been so frequently quoted. If almost all cases of silicosis die of tuberculosis, should the death rate be as low as 1095.5 per 100,000? Although Hoffman's figures could not be a true picture of the tuberculosis death rate in silicosis, it would be interesting to find the prevalence of tuberculosis in the 100,000 cases of silicosis he reported.

This can be done by the use of the formula as described by Mr Drolet⁴ in his section of Epidemiology in Goldberg's system of tuberculosis. By multiplying the rate per 100,000 by five, the incidence of clinical tuberculosis is obtained. In other words, for every tuberculous death there are five living cases of clinical tuberculosis. Hoffman's 1095.5 per 100,000 would be 54 per cent. It has also been pointed out that where the death rate in tuberculosis is increased, as in the negro, because of the acuteness of the disease and the frequency of occurrence, there may be only three living tuberculous patients per death. Therefore, it would be more logical to multiply the 1095.5 per 100,000 by the figure three. The prevalence then would be 3.2 per cent. It has been previously mentioned that Hoffman's death rate is probably too high.

We have few statistics of tuberculosis among workers exposed to silica dust. In most of the instances, there are too few details mentioned of the mode of examination and too much of the term "silico-tuberculosis" used for diagnosis. There are two groups in this country in which the work was carefully done. Smith and Fennel,⁵ in a study of silicosis among rock-drillers, blasters, and excavators in New York City, examined, x-rayed, tested the sputum, and even tuberculin-tested the workers. They reported six cases of active pulmonary tuberculosis in 208 workers. Two of the six cases had no silicosis. Therefore, there were four out of 204 men with active pulmonary tuberculosis, or 1.9 per cent. These figures are very close, but less than the incidence of tuberculosis in food-handlers as recently reported by Martin, Pessar, and Goldberg.⁶ This group reported a similarly well-managed examination of two thousand apparently healthy food-handlers. The group was composed of both men and women. In the first one thousand examined, the men formed the majority of the workers, and thirty-six, or 3.6 per cent, of active pulmonary tuberculosis was discovered. They also reported that if the incidence were expressed by parenchymal pathology as found by x-ray, of the first thousand, twelve per cent had tuberculosis, and of the second thousand, eleven and eight tenths per cent. In the second thousand cases there were

only ten active cases of pulmonary tuberculosis, reducing the percentage from 3.6 per cent to 2.3 per cent.

In an examination of 7722 miners in the lead and zinc mines of the Pitcher field of the Tri-State district (Oklahoma, Kansas, and Missouri), Meriwether, Sayers, and Lanza⁷ report 3.4 per cent of silico-tuberculosis in 1928 and 2.6 per cent in 1929. They also report finding 1.34 per cent of pulmonary tuberculosis without silicosis in 1928 and a reduction to 0.89 per cent in 1930. It is difficult to correlate the incidence of tuberculosis in the silica dust occupations with the statements that most silicotics die of pulmonary tuberculosis.

The same is true with the current belief that silicosis predisposes to tuberculosis. When does the susceptibility to tuberculous infection begin to manifest itself? Is it logical to believe that silicosis predisposes to tuberculosis when there is the frequent history of twenty to thirty years exposure to silica dust before the sudden development of an acute caseous pneumonic tuberculosis? Why had not the tuberculosis developed in the first years of silicosis? Although it is difficult to turn away from the present concepts of tuberculosis and silicosis, the question merits considerable thought.

Conclusion

1 A diagnosis of silicosis must be based, first, upon a history of sufficient exposure to silica dust.

2 The simple and uncomplicated forms of silicosis are easily diagnosed by x-ray examination.

3 The far-advanced and complicated forms of infective silicosis are difficult to differentiate from pulmonary tuberculosis by x-ray.

4 In far-advanced silicosis the continued absence of tubercle bacilli in the sputum is a sufficient factor to rule out the diagnosis of clinical pulmonary tuberculosis.

5 The accepted fact that most patients with silicosis die with pulmonary tuberculosis is grossly exaggerated. It is difficult to correlate the rather low incidence of tuberculosis in silica dust occupations (1.8 per cent to 5 per cent) with the statements that most silicotics die of pulmonary tuberculosis.

CLINICAL FEATURES AND INDUSTRIAL SIGNIFICANCE OF SILICOSIS

A J LANZA, M D, *New York City*

Assistant Medical Director, Metropolitan Life Insurance Company

The following definition of silicosis was promulgated by a Committee of the American Public Health Association in 1932

Silicosis is a disease due to breathing air containing silica (SiO_2), characterized anatomically by generalized fibrotic changes and the development of milary nodulation in both lungs, and clinically by shortness of breath, decreased chest expansion, lessened capacity for work, absence of fever, increased susceptibility to tuberculosis (some or all of which symptoms may be present), and by characteristic x-ray findings¹

While not entirely satisfactory, this definition has been generally accepted in this country although it is probable that it will be revised in the near future. It should be understood that the definition applies to dust containing free silica, that is, silica which is not in chemical combination with other substances. As far as we know now, dusts containing silicates, with one exception—*asbestos*—do not cause a disabling pneumoconiosis.

It should also be understood that the effect of the inhaled silica dust upon the lungs is, so to speak, a mass action and quite different from an infection. The pathological effects of the inhalation of silica dust are apparent from the earliest inception of the disease throughout all of both lungs. Although x-ray films may on account of the anatomic structure of the body, show the characteristic nodulation as more apparent in one part of the lung than in another, postmortem examinations of even the earliest cases reveal that the distinctive process is evenly distributed throughout the lungs. One does not look, therefore, for a localized area of silicosis in one lung as would be done in the case of an infectious process.

Silicosis is a truly occupational disease and does not occur except as an occupational disease. It is found among the following classes of industrial workers

1 Those who mine in hard (silicious) rock—gold, silver, copper, lead, zinc, iron, particularly those workers who are engaged in drilling, shoveling, blasting—underground—and crushing rock and ore above ground.

2 Those whose occupation is of the nature of mining—workers in tunnels, foundations, and quarries, where the work is carried on in silicious rock. The essential process is similar to mining, that is, holes are drilled in rock with pneumatic drills, the holes are then loaded with dynamite and blasted, and the resulting broken rock and debris are shoveled away.

3 Those whose work consists of cutting and dressing highly silicious stone, for instance, granite monument works.

4 Those who work in industries where there may be processes which involve exposure to silica dust. Such processes are very numerous indeed and are to be found in glass works, pottery works, foundries, refractory works, abrasive works, and in grinding and sandblasting.

It is not possible to make more than a rough estimate of the number of industrial workers in this country who are exposed to the silica dust hazard, but it is probable that this number is at least 500,000.²

Our knowledge of silicosis is largely derived from the results of surveys and investigations undertaken in the industries where the hazard is to be found, notably the hard rock mining industry. The clinical picture, when so studied, varies according to the severity of the hazard, hence, the clinical picture in one location will differ from that in another location but will, in each case, be fairly constant. The severity of the hazard depends upon the degree of dosage of silica, and to appreciate this, one must know the

amount of silica in the rock or other substance with which the individual works. This may be quartz containing practically one hundred per cent free silica, or granite containing fifty to sixty per cent free silica, or some mixture of sand or other abrasive substance which may contain only twenty to thirty per cent free silica. The next essential point in estimating the severity of the hazard is the determination of the amount of dust present. In this country, dust samples are collected by the standard technic elaborated by the United States Public Health Service and the United States Bureau of Mines. The result is expressed in millions of particles under ten microns in size per cubic foot.

The silicious dust in any given instance, therefore, may be present in terms of hundreds of millions of particles per cubic foot or in very much smaller amounts. This, of course, has a practical bearing upon the dosage. We must consider also that the patient's exposure may be constant or intermittent—intermittent either on account of the nature of the work itself or because the workman is accustomed to seek employment in the harvest fields or other outdoor work at certain seasons of the year.

The importance, therefore, of a very careful occupational history of any patient in whom silicosis may be suspected or diagnosed is at once apparent. Remembering that silicosis takes years to develop, it must be appreciated that perhaps neither the present occupation nor the immediately previous occupation of a patient may be responsible for his condition. When a silicosis survey is carried on and the individuals examined are men still working at their daily job or perhaps recently disabled, the occupational factors can usually be determined fairly accurately. But when the individual patient is picked up in the ward of a general hospital, it is by no means so easy to determine whether his condition originates from his employment. Such a patient may be quite ignorant of any health hazard to which he may have been exposed. Even though the physician can ascertain that he was at some time exposed to silica dust, the extent of the hazard may be largely a matter of guess work. If such a ward patient has silicosis, his disability may be due to a complication of

diseases not directly referable to his occupation, rather than to silicosis.

Where the silica hazard is very severe, as was formerly seen when pneumatic drilling was carried on in a highly silicious rock without the use of water or other means to entrap or allay the dust, disability more or less complete may develop from the resulting fibrosis of the lungs without a complicating infection. Such extreme hazards are uncommon and are tending to disappear.

Generally speaking, the type of silicosis seen in American industries today does not, as a rule, cause disability unless the factor of infection is present. We still do not know why the silicotic individual tends to become tuberculous but that he does so is attested by the overwhelming evidence of every country or locality where this disease has been studied. Infection may manifest itself by the typical symptoms of night sweats, loss of weight, profuse sputum, and moist rales. On the other hand, infection may not be made evident, clinically, until it is very far advanced.

Where the silica hazard has been very severe, when tuberculosis infection occurs, the patient is apt to go down hill very rapidly. Otherwise, the silico-tuberculosis tends to pursue a chronic and slowly disabling course.

One of the dilemmas that confronts the physician is the advice that he should give his silicotic patient about continuance at his work. The situation here is complicated by various economic considerations and it is not practicable to be too dogmatic in laying down rules and regulations. If the silicotic patient has active tuberculosis, he should, of course, be advised to quit work both for his own sake as well as that of his fellow employees. If he has a definite silicosis and it is not possible in his present occupation to avoid further exposure to the hazard, evidently his best chance of holding his disease in check is to seek other employment. If, on the other hand, having been detected by the employer and adequate provisions made to control the hazard, the patient might as well continue in the work for which he is fitted and trained as to seek other employment, particularly if he is along in years. This whole matter of working or quitting work is far from a

simple one and calls for very careful and conscientious thought on the part of the physician who is called upon to render a verdict

Needless to say, the x-ray film is the principal reliance in diagnosis, and stereoscopic films are essential, especially in the early cases. Without the characteristic appearance of nodulation, the diagnosis cannot be made. A careful occupational history will often save the diagnostician from embarrassment. Those interested might well consult the Committee Report entitled "Roentgenological Appearances in Silicosis and the Underlying Pathologi-

cal Lesions," which was published in the *United States Public Health Reports* for August 2, 1935

There is a growing amount of evidence to show that when negroes are exposed to severe silica hazards, they may succumb quite rapidly. An overwhelming tuberculous infection may be set up even before the characteristic fibrosis due to the inhalation of silica is well-established

BLOOD DONORS TRANSMIT MALARIA

Two interesting cases of malaria that were transmitted by blood transfusions thirty-three years after the donor of the blood had recovered from the disease are reported in *The Quarterly Bulletin* of the New York City Department of Health. The first case was that of a child who received a transfusion of blood donated by its father. Twenty-nine days later the child developed malaria. Questioning of the father revealed that he had been ill of malaria in Greece thirty-three years ago but had been free of symptoms since that time. The second case was that of a woman who, after an operation, received a transfusion of blood from her husband. She developed malaria eleven days later and questioning revealed that her husband had had the disease in Palestine thirty-three years ago and had since been symptom free. In both cases examinations of the blood of the father and husband were made and in each case no trace could be found of the presence of malaria parasites.

* The germ that causes malaria is usually transmitted by the anopheles mosquito. The mosquito, which seems to suffer no ill effects from the presence of the germ in its body, becomes infected with it when he draws blood from the body of a person who has the disease. When a mosquito bites a person the first operation is to inject an acid fluid which thins the victim's blood at the point of attack and make it easier for the mosquito to draw out the blood. It is in this course of this injection that the mosquito carrying the germ passes it to the new host and thus spreads the disease.

The occurrence of these two cases in which the presence of the malaria germ in the transmitting blood could not be demonstrated seems to indicate that there was present in the blood some other factor than the germ, which factor has the ability to produce the disease in a body not supplied with the immunity factor that it creates and which, it appears, is not transmitted with the disease-producing factor.

WASSERMANN TEST CUTS MARRIAGES

Since Connecticut's law requiring blood tests before marriage went into effect last January, weddings in the state have dropped to approximately half the number that there were before, reports the *New England Journal of Medicine*.

The State Department of Health figures show that during the first five months of the year, from January through May, 1813 marriages were performed in Connecticut. In the same five months of 1935 there were 3,468 couples wed. This is a drop of more than 47 per cent.

The marriage law requires both the man and woman applying for a marriage license to present a doctor's certificate showing that

the applicant has submitted to a blood test for syphilis and that the reaction has been negative. The specimens of blood may be examined in any laboratory approved for that type of work by the Health Department, and only a part of the specimens go to the department's own laboratory in Hartford.

The sharpest decline in marriages has been in the border towns, indicating that fewer people are coming into Connecticut from other states to marry. The Health Department has no figures yet to indicate how many Connecticut people are going outside the state to marry this year. Information from other states will be secured after the law has been in effect longer.

A STUDY OF THE BALL TECHNIC OF ROENTGEN PELVICEPHALOGRAPHY

FERDINAND J. SCHOENECK, M D, LEE HADLEY, M D, and
ALBERT VANNESS, M D, *Syracuse*

Considerable interest has been evinced during the past decade on the subject of x-ray pelvimetry. Last year, Ball and Marchbanks^{1,2} of Chattanooga, Tenn. developed a technic which depends essentially on a volumetric comparison of the fetal head and the pelvis thru which it must pass.

Two x-ray plates—an anteroposterior and a lateral—are taken at a specified distance. The circumference of the head is measured on each plate. The volume is estimated from the circumference. The mean of these two measurements, expressed in milliliters or cubic centimeters, represents the volume of the fetal head.

The shortest anteroposterior diameter of the inlet—conjugate vera—is computed from the lateral plate. Using this measurement as the diameter of a sphere, the volume of such a sphere is determined. This procedure is repeated, using the narrowest transverse measurement of the mid-pelvis—the bisischial—on the anteroposterior plate. The smaller of these volumes is used for comparison with the volume of the head.

If the volume of the fetal skull is greater than the smaller of the estimated pelvic volumes, the result is expressed in terms of + milliliters or cubic centimeters, if the fetal skull volume is smaller, the reading is given as—milliliters or cubic centimeters.

The curvature of the sacrum and width of the sacrosciatic notch should receive careful attention in evaluating the size of the pelvis at the level of the ischial spines. Caldwell³ has emphasized the importance of these observations in interpreting the capacity of the posterior portion of the pelvis.

No direct information as to the pelvic outlet is available by this method of pelvimetry.

One might naturally deduce that if the volume of the head is greater than that

of the pelvis, there will be difficulty in delivery. However, other factors enter into such deductions. Nature is able to take care of most minor disproportions by means of the well-known mechanism of labor in association with molding of the head. We may not, therefore, conclude that all + readings by Ball's method will give rise to dystocia.

In regard to interpretation of findings, we shall quote from a personal communication from Dr. Ball.

In manuscripts which are to be published, I have emphasized that disproportion of 150 ml (+150) with the true conjugate diameter, is a true disproportion. However, a disproportion of 250 ml with the bisischial spine diameter may not be of consequence, provided there is a wide sacrosciatic notch and well-curved sacrum. In the narrow notch with straight sacrum and small posterior pelvic capacity, rotation may be impossible, and in this type of pelvis the bisischial spine diameter should not show a disproportion greater than that tolerated by the fetal head through molding. This maximum toleration is about 150 ml.

We are presenting a study of fifty cases, x-rayed according to the Ball technic. Most of these women were x-rayed early in labor. The plates, however, were not interpreted until after delivery, consequently the conduct of these cases was not influenced by the roentgenological findings.

TABLE I—OPERATIVE INCIDENCE

+ Cases	(18)	36%
— Cases	(32)	64%
Entire Group	(18 of 50)	36%
— Cases	(6 of 32)	18%
+ Cases	(12 of 18)	66%
Over +50	(6 of 7)	85%
Over +150	(3 of 3)	100%

Table I represents the operative incidence of the group. Thirty-six per cent of this series fell in the + group, i.e., the head was larger than the pelvis. This figure is probably not a true index of the general per cent of plus cases, since, in the latter part of the study, we x-rayed only those women who had some clinical evidence of disproportion. This fact accounts

Aided by a grant from the Hendrick's Research Fund—College of Medicine, Syracuse University

also, for the high percentage of operative deliveries in the entire group, i.e., thirty-six per cent. We have included as normal, spontaneous deliveries and true prophylactic forceps. All other deliveries were considered as operative.

The difference in operative incidence between the minus and the plus group is quite marked. As a matter of interest, we have compiled the incidence of cases above +50 and above +150.

Table II represents the average length of labor in the plus and minus groups. While we recognize that many other factors—presentation, position, and condition of the soft parts—influence the length of

47	12	42hrs.		+295	Large post. pelvis Version and extraction.

labor, the contrast does seem to be of some significance.

Table III is an analysis of the operative cases in the minus group. Bony disproportion may be definitely ruled out in Cases 28, 19, and 48. In case 45, laparotrachelotomy revealed an apparent anomaly of the bladder, which may have interfered with descent. Clinically, case 34 was a true cervical dystocia. Case 24 is illustrated in Fig 1. While there is no disproportion, it will be seen that the pelvic inlet is practically on the same plane as the vertebral column. In attempting engagement by fundal pressure, it can be seen that the head is forced against the pubis, rather than being directed into the pelvic cavity.

Table IV represents the + cases that delivered normally. The readings at the inlet and mid-pelvis are given. It will be noted that Case 1, a Grav IV, was the only case with a disproportion greater than fifty ml that delivered spontaneously.

Table V represents the + cases that were terminated by operative deliveries.

CASE 6. The mid-forceps extraction in this instance was probably due to the faulty attitude of the head rather than any true disproportion.

CASE 17 (Fig 2). This patient had a clinically diagnosed contracted pelvis with a true conjugate of 10 cm. Engagement of the head was attempted with the patient anesthetized. The head could not be engaged and a cesarean section was elected. Study of the x-ray plates failed to reveal a true disproportion and it would seem that the extended attitude of the fetal head accounts for the unengagability.

CASE 50 (Fig 3, 4). This patient had a flat rachitic pelvis—true conjugate 8.75 cm. transverse of the outlet 9.5 cm., posterior sagittal 6.5 cm. Membranes were ruptured after seven hours of labor—the head was unengaged and unengagable. Two hours later conditions were unchanged and it was decided to deliver by laparotracheotomy. At this time the x-ray plates were studied. According to the Ball technic, no true disproportion existed, however, the abnormal curvature of the sacrum produced fear that there might be difficulty at the outlet (clinical mensuration showed an index of the outlet of sixteen, which is adequate).

Fig 1 Abnormal inclination of pelvis (Case 24)

This patient was examined, just before she was to be placed on the operating table, and the head was found to be definitely engaged. She was delivered by a simple low forceps extraction five hours later.

CASE 42 There was no true disproportion at the spines or inlet. The outlet was definitely contracted.

CASE 23 Preeclamptic toxemia. Labor was induced by means of bag insertion. The child was delivered by manual rotation and high forceps extraction when the cervix was five fingers dilated. No true disproportion was present.

CASE 3 The minor disproportion at the inlet

Fig 2 Fetal head in extension attitude (Case 17)

was apparently compensated for by molding of the fetal skull.

CASE 35 This was a clinically diagnosed border line pelvis. The head was asynclitic. After a forty-one hour test of labor, a laparotomectomy was done. When the abdomen was opened, free blood was found and examination of the uterus showed a beginning rupture. The patient made an uneventful convalescence.

CASE 15 This was a laterally contracted pelvis. Clinically the outlet was also contracted. Position R.O.P. with failure to rotate. The child was rotated manually and delivered by axis-traction. Delivery was very difficult. The child died as the result of a cerebral hemorrhage.

Fig 3 Flat, rachitic pelvis, anteroposterior view (Case 50)

Fig 4 Flat, rachitic pelvis, lateral view (Case 50)

CASE 2 Rhachitic pelvis All previous deliveries had been instrumental The outlet was adequate. Delivery was successfully accomplished with forceps

CASE 43 Male type pelvis Contraction at the inlet. Patient was sectioned after sixteen hours of labor X-ray study revealed a true disproportion at the inlet.

CASES 45 and 47 These cases illustrate two laterally contracted pelvises (Fig 5, 6) Case 45 was delivered by cesarean after a twenty-eight hour test of labor Case 47 was successfully delivered by version and breech extraction Examination of the x-ray plates shows a marked difference in the posterior portion of the pelvis Case 47 shows a well-curved sacrum with a wide sacrosciatic notch, whereas in case 45, the sacrum has an abnormal curvature and the sacrosciatic notch is more acute.

one instance of true disproportion at the inlet—this case was sectioned Two cases showed a disproportion of over +250 at mid-pelvis In one instance the posterior portion of the pelvis was not adequate and the patient was delivered by cesarean, in the other case, a gravida 12, the posterior portion of the pelvis was adequate and this child was delivered by version and extraction

Two cases were delivered by cesarean section because of clinically diagnosed bony disproportions X-ray studies revealed no true disproportion In one instance there was an abnormally inclined

Discussion

Ball's method of pelvicephalography is comparatively new Further study will be necessary before its true value can be determined

Ball feels that a disproportion of 150 ml at the inlet constitutes a true disproportion In mid-pelvis, he states that 250 ml may not be a true disproportion, providing the posterior half of the pelvis is adequate He feels, further, that the head usually is able to mold sufficiently to overcome a disproportion of 150 ml

Our study has shown that we may expect a definitely increased operative rate with heads that show + readings Eighty-five per cent of the cases over +50 ended with operative deliveries We had

pelvis and in the other the head was in a faulty attitude

There were two fetal deaths in the group, one due to cerebral hemorrhage following axis-traction forceps with a +61 disproportion, the other to fetal distress without disproportion

In one instance a patient was scheduled for a cesarean The x-ray study failed to show a disproportion With our present limited knowledge of this method, it is probably not fair to say that this new adjunct saved this particular patient from section It is fair to say, however, that the x-ray study was a big factor in producing a very careful and minute study of this case

We shall make no effort to draw con-

clusions from this small series of preliminary studies. We do feel, however, that the results have been promising enough to warrant a thorough clinical investigation.

It would appear that this method may be of definite value in determining those cases of disproportion which should be terminated by cesarean section. It cannot be emphasized too strongly, however, that with our present knowledge, x-ray pelvimetry, alone, must not be relied on to solve this problem. There can be no question that the improper use of x-ray pelvimetry will lead to many unnecessary cesarean sections.

On the other hand, it would seem that

the Ball method of pelvicocephalography, if used in conjunction with the clinically proven procedures, namely pelvic mensuration, test of engageability and test of labor, will be of great value in determining the proper treatment of bony disproportion.

We wish to acknowledge cooperation of the Roentgenological Department of the College of Medicine, Syracuse University.

VITAMIN C VALUE IN ORANGE AND TOMATO JUICE

Orange juice contains from two to three times as much vitamin C as tomato juice. Either of the juices loses vitamin C if allowed to stand before using. These results are announced by workers in the Bureau of Home Economics, U. S. Department of Agriculture. The Bureau points out, however, that when tomato prices are much lower than orange prices, it may be possible to get as much or more vitamin C protection per dollar from tomatoes. The tests included both chemical analysis and feeding trials of four varieties of oranges, two from California and two from Florida—fresh pressed juice of tomatoes and juice from a brand of commercial canned tomatoes. The juice of the California navel oranges was slightly richer than the others but some of the others were enough juicier so that the juice from a fruit of equal size gave as good or better protection. To obtain the same protection from tomato juice it would

be necessary to give two or three times as much juice.

The investigators, Esther Peterson Daniel, Mary H. Kennedy, and Hazel E. Munsell, found that the canned tomatoes which they tested contained as much vitamin C as the fresh sample. These tomatoes were grown in different sections of the country and since there is a loss of vitamin C in canning these results raise the question of the effect of soil and climate upon the amount of vitamin C formed in the plant.

The common household custom of squeezing orange juice at night to serve at breakfast causes a loss of ten per cent or more of its vitamin C value even though it stands covered in a refrigerator. Tomato juice from fresh or canned tomatoes also deteriorates when allowed to stand exposed to the air. This may amount to as much as a forty per cent loss if the juice stands for several days.

PSYCHOLOGY OF CAR DRIVERS

Dr. Richard H. Hutchings, superintendent of Utica State Hospital at the request of the commissioner of safety of the city of Utica, recently made a noteworthy statement relative to the psychology of car drivers, says the *Mental Hygiene News*. The following is an abstract of the statement:

It is a familiar experience that a person has a tendency to enter into the situation in which he finds himself and assumes a new personality different from what his ordinary one is at other times.

When one gets behind the wheel of a high-powered automobile, the power within the machine itself enters into his personality. The power which he can generate in the machine becomes transferred to power within himself. His ego becomes enlarged, he is all powerful

the rights of others become in the same degree insignificant, he becomes impatient with anything that balks or hinders him, such as slow traffic and red lights. It may be said that he has become intoxicated with a feeling of power—almost of omnipotence.

In this mood, a pedestrian is an annoyance to him. The pedestrian has no right to get in his way and he will take chances in his driving which he knows are dangerous, but which he disregards under the influence of his exaltation. We see somewhat the same thing with men under the influence of liquor. Such men, in proportion to their emotional maturity, have a tendency under provocation to be boastful and offensive to others. When one puts together a moderate amount of liquor and a high-powered machine a combination results which is a real menace to the safety of others.

SIMPLE MILK MIXTURES IN THE FEEDING OF PREMATURE INFANTS

ABRAHAM TOW, M D, *New York City*

Adjunct Professor of Pediatrics, New York Polyclinic Hospital and Post Graduate Medical School

Many types of feeding mixtures have been recommended as suitable for the premature infant. The basis of most of these has been breast milk. It is given alone, combined with evaporated milk in varying proportions, or is reinforced by the addition of carbohydrate. But breast milk should not be looked upon as the *sine qua non*. The doctrine has often been promulgated that it is the only safe food for prematures and that any success with artificial mixtures is solely a matter of luck. Such a belief is a relic of the days when unhygienic methods in the collection, transportation, and storage of cows' milk often made it unsafe for human consumption, especially for those born before term. These conditions still exist in certain communities, but when one can be assured of clean cows' milk, its use in the feeding of premature infants is safe and, for many reasons, often desirable.

There can be no quarrel with the stand that breast milk is the most desirable food for the normal newborn infant, but with the premature, certain other factors must be considered. Breast milk is at times difficult to obtain as the child's own mother generally leaves the hospital after two weeks and milk from other patients may not be available. If the mother has to pump her own breasts and deliver the milk she may be unable for economic or

physical reasons to do so. Mothers' milk may be purchased but it is expensive and such an expense is often a burden to the family. In addition, breast milk containing but 1.5 per cent protein hardly seems suitable for the needs of such a rapidly growing organism as the premature infant. Therefore, in spite of the fact that an imposing array of statistics has been advanced to prove that breast fed infants are less likely to suffer from respiratory and gastrointestinal disorders than those artificially fed, it is felt that the sacrifices usually made to obtain breast milk are hardly necessary, especially since adequate substitutes are readily available. A feeling has existed that cows' milk could not be satisfactorily used as one of these substitutes and it is to call attention to the fallacy of this position that this contribution is offered.

In our hands milk mixtures with from eight to seventeen per cent carbohydrate and one to three per cent added protein, have proven extremely efficacious. The results with such formulae have been as good, if not better than those reported with the use of any of the other artificial foods or with breast milk, either alone or reinforced. Before presenting these observations it would be proper to state that of all the considerations entering into the care of the premature infant, nursing supervision is without question the

most important, more important even than the incubator or the type of food employed

During the past few years sixteen consecutive infants weighing less than four pounds at birth have come under our care as private patients. Those of four pounds and over have been deliberately eliminated because they usually do well and so help bolster the figures of a statistical study.

Five of the sixteen patients failed to survive. A study of Table I best illustrates the findings and the causes of death.

In the next group, consisting of five patients, pooled breast milk reinforced with seven to ten per cent dextri-maltose was given for a period of from three to seven weeks. Simple milk mixtures with high caloric feedings were gradually sub-

stituted. The findings can readily be observed by a study of Table II.

The third group consisted of six infants who received milk mixtures from the very beginning. The practice was to start with one-half milk and one-half water reinforced with dextri-maltose. Feedings were given every three hours commencing six hours after delivery. A five per cent sugar solution was also given every three hours, alternating with the formula. The patient thus received fluid every one and one-half hours. As the amount of formula taken gradually increased, the water feedings were decreased. Three of these infants received formulae containing an additional one to two per cent protein in the form of calcium caseinate and in one infant three per cent was added at the twelfth week, following which the weight gain,

CHART II

petite of the premature is capricious. The amount taken at each feeding varies, especially during the first two weeks of life. This can readily be appreciated by a study of Table IV which shows the intake in drams at various stages during the first month of a male infant, seven months gestation, birth weight three pounds

That the fluid intake of all prematures is not the same is quite evident. The amount taken by an eight month old pre-

mature, birth weight three pounds, eight ounces, far exceeded that in the previous case. By the second day he was taking from six to eight drams of the formula at each feeding with three to six drams of water in between, and by the end of the first week his fluid intake was almost one-fourth of his body weight. Naturally, the closer the fetus is to term the more he may be expected to take, all other things being equal

CHART III

Comment

From a study of the last group it was felt that simple milk mixtures reinforced with eight to seventeen per cent carbohydrate were safe and gave excellent results in the feeding of premature infants. The use of added protein in the form of calcium caseinate from one to three per cent seemed to accelerate this gain. A study of Charts I-III will illustrate the type of feeding and the progressive gain in weight. Attention is called to the high caloric intake. Feedings of as much as 120 calories per pound were given without upsetting the tolerance. The maximum amount of carbohydrate added was two ounces. The added protein was usually discontinued towards the end of the third month.

Conclusions

Simple mixtures of cows' milk with eight to seventeen per cent added carbohydrate in the form of dextri-maltose No 1 and one to three per cent added protein in the form of calcium caseinate have been found highly satisfactory in the feeding of premature infants.

Such mixtures with high caloric values, even up to 120 calories per pound, caused an average gain of one ounce daily from the low point in six premature infants whose average birth weight was three pounds two ounces. The average period of observation in the hospital from the low point was fifty-three days.

1085 PARK AVE.

HIGH LIGHTS AND LOW LIVES

A Detroit physician stated "If I want to give away my money, I should be the person who will dictate where that money is going, but if I want to give away my time in a dispensary, I find myself the only person who has absolutely nothing to say about it. That is why I'm now dispensing my charity service in my office and not in a so-called free clinic."

The American Indian "now has a birth rate that is probably the highest in the world," and his death rate is declining, according to Dr. Clark Wissler of Yale. Meantime the white birth rate is falling. If these trends continue, which will control the America of the future?

A woman went to see a doctor. "Doctor," she exclaimed loudly, bouncing into the room, "I want you to say frankly what's wrong with me."

He surveyed her from head to foot. "Madam," he said at length, "I've just three things to tell you. First, your weight wants reducing by nearly fifty pounds. Secondly, your beauty would be improved by freer use of soap and water. And thirdly, I'm an artist, the doctor is on the next floor."—*Montreal Star*

Freud, strangely enough, almost became the discoverer of cocaine anesthesia, says a writer in the *New York Times*. This discovery of Karl Koller's, hailed by an ad-

miring world in 1884, was based directly upon observations made by Freud in an essay upon the properties of the coca plant which he had published in the "Zentralblatt fuer Therapie."

Appointment of Dr. Nolan Don Carpenter Lewis as director of the State Psychiatric Institute and Hospital, a unit of the Columbia-Presbyterian Medical Center in New York City, is announced. He has been assistant professor of neurology at Columbia University and associate director of the Neurological Institute.

The best ten years of a woman's life lie between the ages of twenty-eight and thirty.—Health Digest

No outbreak of typhoid fever due to a contaminated public water supply has occurred in this State in five years, reports the State Health Department. Deaths from typhoid reached a new low point of 5 per 100,000 in 1935, only 316 cases were reported in that year.

Dr. Harold L. Barnes, Chairman of the Kings County Medical Milk Commission for the past six years, was elected President of the American Association of Medical Milk Commissions at the close of that body's recent annual joint conference with the Certified Milk Producers' Association of America, held in Kansas City.

THE PLACE OF SURGERY IN THE THERAPY OF PEPTIC ULCER

URBAN MAES, M D, and ELIZABETH M McFETRIDGE, M A, *New Orleans, La*
From the Department of Surgery of the School of Medicine of Louisiana State University

To one about to embark by invitation and by explicit direction upon a discussion of peptic ulcer, it is depressing to recall Wensky's comment that one year's crop of papers on that subject simply repeats the crop of former years. It is depressing, I say, because one realizes how perfectly one's own remarks fit into such a category. But repetition is sometimes commendable, especially when, as in this instance, it involves self-examination. It is part of our duty as physicians, it seems to me, to pause at intervals to take stock of our endeavors, to examine first principles in relation to results, and to analyze our experiences as contrasted with our impressions, which latter, in medical literature and practice, are often prone to masquerade as facts.

No more acrimonious debate has enlivened the annals of medicine than the argument between physicians and surgeons as to how peptic ulcer should be treated, and both parties to it have every reason for self-reproach. The surgeon has been so occupied with details that he has lost sight of principles, and his technic has frequently far outstripped his judgment. The medical man, on the other hand, has assumed credit for cures which nature wrought, or has reported as cures ulcers which never existed, and he has ignored entirely the mortality which followed his efforts at therapeutics.

I have recently analyzed 107 consecutive deaths from peptic ulcer from the records of the New Orleans Charity Hospital, and I know whereof I speak. Only seventeen of those deaths followed surgery which even by courtesy could be called elective. The other ninety deaths were due to the catastrophes of ulcer, sixty-nine followed perforation, thirty-two without benefit of surgery, and twenty-one followed hemorrhage, which in nineteen cases was treated only by medical measures.

Statistics may lie, statistics may confuse the picture, statistics may not tell the whole story. But granting those

things, the fact still remains that ninety of these 107 patients lost their lives from the accidents of ulcer, and more than a third of them were admitted moribund. Yet more than two-thirds of them gave a clear-cut history of ulcer and an equally definite story of some sort of medical treatment for it. All deaths which follow surgery must, I suppose, be classified as surgical deaths, but I have never been able to see why the physician who treats a patient up to the time he falls into the hands of the surgeon moribund or almost moribund from one of the accidents commonly associated with peptic ulcer should not at least share with him the onus of what happens.

There is no doubt that medical and surgical measures should be complementary and not antagonistic. There is no doubt that peptic ulcer is essentially a medical condition which requires surgical interference only after properly directed non-surgical measures have failed to bring relief. There is no doubt that always after surgery strict medical supervision is necessary, sometimes for a very long period of time. To be more specific, medical treatment is particularly indicated in all fresh or recent ulcers, in practically all young subjects, in most cases in which the disease is mild and the periods of exacerbation few and brief, in most nervous, high-strung individuals of the so-called ulcer type, who are not permanently benefited by any mode of therapy and whose symptoms are best controlled by medical measures, in poor risks, and finally, in all patients who have the leisure and the money to make a fair trial, or repeated fair trials, of nonsurgical treatment, provided that they understand exactly what chances and risks it involves. If they understand the decision they are making, the right of choice is most certainly theirs, and there can be no quarrel with their medical advisers.

But the acceptance of these indications does not by any means carry with it the

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 29, 1936*

acceptance of the claims made by some medical men for the management of peptic ulcer by nonsurgical measures. In the first place, many cures have been claimed for conditions which were not ulcers. It may seem a foolish qualification, Lord Moynihan says, to demand evidence of an ulcer before accepting the statement that it has been cured, but an ample acquaintance with the literature dealing with the supposed healing of fictitious ulcers makes him doubt—just as it makes any thinking reader doubt—whether this simple necessity is adequately recognized by many writers. Even with the most expert diagnostic methods there is still a large percentage of error. I do not care to recall the number of times I myself have opened the abdomen confidently expecting to find an ulcer, only to find something else, or sometimes nothing at all, and my experience makes me believe that the same fallacy must be present in many reports of cures in which only medical methods were employed and there was no direct proof of the diagnosis.

In the second place, I am unwilling to accept cures by medical measures when I know those measures are inadequate in themselves or have not been employed sufficiently long to make the cures credible. Operative evidence has shown that it is most unusual for an ulcer to heal completely under six months, and that some ulcers take three years or more. Relief follows much sooner, however, and we all know the difficulty, when a patient is relieved of his symptoms, of making him adhere strictly to the regimen necessary to correct his pathology. Sometimes the fault is the patient's, sometimes it is his physician's, but the end-result is the same. He is reported as a cure when he is merely undergoing a remission, which has been brought about more promptly by medical measures perhaps, but which is still only a remission. The ulcer is not healed, it will most certainly recur, and there is not the smallest justification for reporting such a case as a cure. I have operated on enough of them to speak confidently on that point.

In the third place, I cannot accept the facile statement that even if medical measures do not succeed, the patient is no worse off. He is distinctly worse, it seems to me, if he has a perforation that

carries him to the gates of death, or a hemorrhage that carries him through them. Those complications, pancreatitis, varying degrees of obstruction, all can occur under competent medical treatment and are likely to occur under the incomplete variety, which is the variety most usually practiced. Can a patient be regarded as cured, or even relieved, if he must aspirate his stomach every night? I should not consider myself cured under those circumstances, and I fear I should have only a languid interest in the academic distinction between obstruction due to inflammatory exudate and obstruction due to cicatricial tissue. I confess that I cannot quite comprehend the reasoning of the internists who advise this treatment for six months or more, with the proviso that if it fails, and if the patient is a good risk, surgery can then be employed. How he can be expected to be a good risk under those circumstances I do not quite see. And what is to happen to him if he is not a good risk is not anywhere provided for. I recall that in the seventeen deaths in the elective group of the fatal cases I have recently analyzed, four cases, at least, were there only by courtesy. Obstruction was the indication for surgery in them all, but no surgeon in his senses would have elected to operate on any of them had not the choice lain between probable death after surgery and inevitable death from starvation without it.

Finally, I object very seriously to the claim that there is no mortality after medical treatment. Its mortality is at least as high as the mortality for surgical treatment. I personally believe that surgery carries a lower death rate, even in the hands of only fairly expert surgeons, let alone surgeons of such fine judgment and high technical skill as Walton, Lord Moynihan, and the Mayo Clinic group. Are not deaths from massive repeated hemorrhage to be classified as medical deaths? Does not prolonged unsuccessful medical treatment lead the way straight to perforation? For that matter, accidents can occur even under supposedly successful medical treatment. One author, whose name I do not recall, reports eleven doctors who deliberately chose to be treated by medical measures and among whom three perforations occurred, one of which was fatal. Three

patients in the series of deaths I studied perforated in the hospital while they were presumably responding most favorably to supervised medical treatment. Indeed, no more devastating commentary on that subject can be imagined than Vale and Cameron's recent conclusion that the patient who suffers his perforation in the hospital, while undergoing treatment and while surrounded by all the resources of medical science, is more likely to lose his life than is the patient who is stricken in his home or on the street. I cannot agree, I repeat, that medical measures show a zero mortality.

The claim is frequently made that the end-results of medical treatment and the end-results of surgical treatment are the same. Again I cannot agree. That claim is based on a fallacy. It takes no account of the fact that surgery begins where medicine leaves off, and that every surgical case should really be listed as a medical failure. There is no disputing the fact, too, that as time goes on, the percentage of surgical cures is practically stabilized after the first year.

In the recent debate on the subject before the Fellowship of Medicine the decision for or against the medical or surgical treatment of uncomplicated ulcer was practically fifty-fifty. But such abstract debates, of course, prove nothing except that patients who are treated by rule of thumb are not likely to be very well-treated. No sweeping generalizations are possible, such as are permitted in appendicitis, for instance.

Before a continuation of medical treatment, an honest trial of which should always be the first consideration in peptic ulcer, or before a resort to surgery is decided upon, many factors must be taken into consideration. We have mentioned already the age of the patient, his physical and nervous constitution, his family history, his occupation, and his habits of life. There should be considered also his type of ulcer, the duration of his symptoms, and similar strictly medical matters. There should be equally careful consideration of such imponderable factors as the patient's enjoyment of life, and such highly practical ones as his economic status, and the necessity of his earning his own livelihood by the toil of his hands or his brain.

I am among those who consider economic indications a strong reason for surgery. I do not see how anybody, particularly in these days, can fail to regard them as such. There are a dozen applicants for every position, and few employers are likely to look with favor upon employees who must be absent from their work at fairly frequent intervals for fairly long periods of time. Strauss, who studied his cases from this aspect, reports that before medical treatment was undertaken, fifty per cent of his patients were on a fifty per cent earning basis, and that sixty-five per cent who were obliged to undergo repeated medical treatments did not work at all. After surgery—his surgery, I might say, is more radical than I myself favor as a routine—ninety-five per cent had returned to full-time employment within four to nine months.

Medical treatment is always a long-drawn-out method, and often is almost a life sentence. Jordan and Lahey require three weeks rest in bed in the hospital—not always the easy matter it sounds—with a return for observation, fluoroscopy, and estimations of gastric acidity every two months for the next year. Another internist, after the intensive period of treatment, specifies a six-meal bland diet for three years, with other restrictions as to work, rest, and recreation, followed by a permanent mildly restricted diet. Even Alvarez, whose treatment is the simplest and most practical that can be devised, very properly warns his patients that it must continue for an indefinite period. The investment of time and money is always large, and the return is frequently little more than an opportunity for a further and larger investment of the same sort.

My own opinion is that a patient, after a properly supervised trial or after several properly supervised trials of medical measures, should be given the benefit of surgery if he feels that he cannot afford the time and money and cannot so change his life as to continue this mode of treatment. I think the indication is the stronger the more promptly symptoms recur after this form of therapy has been tried, particularly when cicatricial obstruction is present, or persistent pain suggests pancreatic involvement. I would put into the same category ignorant and indigent

patients, patients who lack the will or the intelligence to follow directions literally, and patients who feel that family and business reasons demand their quick restoration to health. In other words, I agree entirely with Lord Moynihan that adequate medical treatment frequently represents a counsel of unattainable perfection, and that the problem is usually not one of medicine but one of social economics.

I do not propose to dwell at any length on perforation as an indication for surgery. Naturally, the acute variety furnishes an urgent indication, and even when the patient is seen after several days, conservative measures should be adopted with a full comprehension of the risk they carry with them. In what majority of ulcers perforation occurs is not definitely known. Graves, from a survey of the world literature, estimates it at ten per cent. The mortality, too, varies considerably, but twenty to twenty-five per cent is a very conservative estimate. The number of lives lost, therefore, is by no means small, and even though there is no way of foretelling in which cases the accident is likely to happen, it would seem that surgery should be done far more frequently than it is to prevent its occurrence. The history is rarely correctly taken on these gravely ill patients, but if it were, I feel sure that a story of digestive disturbances typical of ulcer would be elicited in at least ninety-five per cent of them. I believe, too, that the pre-perforation syndrome could be elicited in a very fair number of cases, and surgery done to forestall it, if only we took the trouble to study the significance of a sudden exaggeration of the usual discomfort and pain. The important thing to note is that perforation is practically always associated with chronic ulcers, and that persistence in medical treatment that has not proved its worth is most certainly a frequent cause of the catastrophe. It is worth remembering, too, that this type of accident is most frequent in the lower social levels, in which, as we have already pointed out, medical treatment is least apt to succeed.

How acute hemorrhage should be treated is still a matter for discussion. Like most surgeons, I have both operated and refrained from operation for it, and

have usually regretted whichever I did. Some authorities take the position that hemorrhage from a peptic ulcer is never surgical, which is in direct contradiction to the principles of controlling hemorrhage elsewhere in the body. It is in direct contradiction, too, to the frequent autopsy finding that the bleeding is caused by a single vessel, which presumably could have been controlled by surgery. Why the advocates of medical treatment should find comfort in the fact that the ulcer is often healed right up to the mouth of the bleeding vessel I have never been able to discover. Some physicians take the position that the first hemorrhage is never surgical. Wilkie advises medical treatment for the first hemorrhage, with operation ten days after the second, and frankly reports the loss of three patients by that plan. Finsterer regards hemorrhage as just as urgent an indication for immediate surgery as is perforation. Rienhoff points out that hemorrhage on the posterior duodenal wall amounts to a posterior perforation into the pancreas and can be benefited only by surgery. Allen and Benedict believe that surgery is always indicated in patients advanced in years, a point of view which my own experience corroborates.

Whatever may be one's ideas as to how hemorrhage from peptic ulcers should be handled, certain facts should be emphasized.

- 1 Bleeding ulcers are a constant source of danger, and, while surgery does not offer one hundred per cent protection, at least the results of elective surgical measures seem to be better than the results of medical measures.

- 2 The teaching that few deaths occur from hemorrhage, especially from the first hemorrhage, is unjustified optimism, about twenty per cent of the deaths at Charity Hospital were due to hemorrhage, and I am sure that proportion holds true in many other clinics.

- 3 Remissions are entirely unreliable, in twelve of the twenty-one deaths from hemorrhage at Charity Hospital there was a fatal recurrence of the bleeding while the patients were apparently well on their road to recovery under medical management.

From that standpoint, then, though I make no pronouncements on the subject, it might seem logical to operate while the patient was still in good or fair condition,

rather than be forced to surgery later, when he was exsanguinated from recurrent hemorrhage

I have never been willing to consider gastric and duodenal ulcers together, and I am gratified to have in that idea the company of such distinguished physicians and surgeons as J M T Finney, Sr, Peck, Merle Scott, Alvarez, Walton, Lord Moynihan, and the Mayo Clinic surgeons. Here I am concerned only with one aspect of that differentiation, the tendency, or the possibility, as you will, of the development of malignancy. That tendency is evident in gastric but not in duodenal ulcers, and I am unwilling to treat gastric ulcers medically on that basis, if no other. I am not concerned with the exact percentage which become malignant, though I cannot share the light-hearted view of those who believe an incidence of five to ten per cent is not sufficient to warrant surgical measures. I share Lord Moynihan's opinion that neither the operative nor the autopsy evidence of the transition is reliable, because the earlier pathologic state is likely to be overlaid by the later malignant disease.

The important consideration, however, is not that some ulcers end as cancer, and some supposed ulcers were always cancer. The important consideration is that even by the most expert clinical and laboratory diagnosis the differentiation between ulcer and cancer is not even approximately accurate. The error may run to twenty-five per cent or higher. In the seventeen elective cases in the Charity Hospital series, operation was undertaken in eight on the belief that the condition was cancer. In 200 surgical cases of cancer which we recently studied from the same institution, fifty of the patients told stories perfectly typical of ulcer, and, more tragic, twenty-nine of them had been treated for it and lost their lives as a result of the mistake.

Generalizations are not safe. It is true that the larger the defect as demonstrated by x-ray, the greater the chance of cancer. It is true that the longer the history, the more likely is the lesion to be benign. Those statements hold for most cases, but are incorrect in enough to make them not only useless but dangerous. A guess, to quote Lord Moynihan again, is a poor peg on which to hang a man's

life. McCarty's figures for the ulcer-cancer transition may be too high, but there is an element of safety in them which is overlooked by those who refuse to accept them. I find Walton's comment very significant, that his percentage of operability in cancer, which reasonably should be higher now than it was ten years ago, actually is ten per cent lower, the explanation being that many cancers were diagnosed as ulcers and were treated by medical measures until they were beyond cure.

If it is often impossible, without microscopic study, to differentiate between ulcer and cancer when the lesion lies before one, it is unlikely that the distinction can be made safely or accurately when the abdominal wall intervenes. Patients with a typical history of ulcer, with laboratory findings typical of it, with a confirmatory radiologic diagnosis, often prove the utter unreliability and worthlessness of that evidence by dying of cancer. Even the criteria set down by Lahey and Jordan and by Scott and his associates are not entirely safe. Response to treatment, even with x-ray evidence of improvement, is not necessarily a proof of benignity. "A degree of clinical silence" may follow rest and dietary management, even in malignant disease, and the period of delay may turn the tide against the patient.

I would not have you believe, however, that I advocate a quick resort to surgery. Far from it. I am entirely without sympathy for the surgeons who undertake dangerous operations, as all gastric operations are, with a light-hearted indifference to their possible consequences. The fact that often death and poor results can be charged to gross personal incompetence and are not really failures of surgery is poor consolation to the victim of these errors if he survives, or to his family and friends if he does not. I firmly believe that much of the unwillingness of medical men to advise surgery for peptic ulcer is due to the tendency of many surgeons to take unnecessary risks. The performance of gastroenterostomy in cases in which the ulcer cannot be demonstrated or for which it is not suitable, is one example. The unnecessary performance of gastrectomy is another. Undoubtedly this operation is justified in most cases of gastric ulcer,

but it is rarely if ever warranted in duodenal ulcer I can see no point to subjecting a patient to a risk several times higher than is necessary in order to protect him against a possible marginal ulcer, when his chances of being cured by less drastic measures are eighty per cent or more. That, says Rienhoff, is like playing the trump card first. Furthermore, I seriously question whether the incidence of jejunal ulcer is as high as some authors make it out, many of them, I note, make no allowance in their estimates for the cured patients who do not return. Dr Finney considers that resection as a punishment for duodenal ulcer is out of all proportion to the crime, and adds that it just goes to show how tolerant to punishment the human organism is.

Ryle, in concluding his excellent paper on duodenal ulcer, says that the physician's most important contribution to its prophylaxis is the general advice to nervous individuals in an age which has largely lost its old simplicities. His most important contribution to its therapeutics, he continues, is the observation of the entire disease and the qualities of its victims, to achieve a wise balance in the choice of therapeutic methods. Dr Finney hits the nail on the head even more exactly—and incidentally deflates a good many medical and surgical balloons—when he says that after all nothing is followed by such satisfactory even if temporary relief as leaving everything and going fishing.

EDUCATION NEVER ENDS

The new President of the Medical Association of the State of Alabama, Dr Charles Alston Thigpen, of Montgomery, took occasion to remind his medical brethren in his inaugural remarks that the physician who assumes the attitude that his education is complete upon receiving a piece of parchment in the form of a medical diploma will prove both a failure to himself and a menace to the community he pretends to serve. At this point he has, in truth, but taken the first step of his professional education, he must continue a student throughout life, preserving and cultivating an analytical and

intellectual attitude towards all problems presenting in the busy routine of his daily life. He must early learn that the practice of scientific medicine of today compels the physician to so enlarge his horizon and his scope of vision as to embrace not only the sick individual but also the family group and the community as well. The cure of disease cannot and should not be separated from its prevention, and the conscientious physician who views his profession as an integral and important part of society finds himself in position to make lasting contributions to his fellowman, regardless of where his lot may be cast.

District Branch Meetings

The Annual Meetings for 1936 have been arranged on the following schedule:

October 1, Thursday—Fifth District Branch—Rome

October 2 and 3, Friday and Saturday—Fourth District Branch—Plattsburgh

October 7, Wednesday—First District Branch—Morrisania Hospital, New York City

October 15, Thursday—Eighth District Branch—Buffalo

November 19, Thursday—Second District Branch—Garden City

DIAGNOSIS AND TREATMENT OF PERIPHERAL VASCULAR DISEASE BY PHYSICAL AGENTS

WILLIAM BIERMAN, M D, *New York City*

During the past few years many advances have been made in the diagnosis and treatment of peripheral vascular disease. Of these, a goodly number have been physical in their nature. It is the purpose of this paper to call attention to some of them.

Physical treatment procedures are essentially physiologic aids. They do not combat the etiologic factors. Yet, they are frequently responsible for the arresting of the progress of the local vascular pathology and for its improvement to an extent which permits restoration of function of the involved extremities.

For many years physical measures have been employed in the treatment of conditions like thromboangitis obliterans and arteriosclerosis. The obviously inadequate peripheral circulation clearly indicated the use of circulation-stimulating heating measures such as heating hoods (so-called "bakers"), hot soaks, hot packs, and contrast baths. These measures, while of great value in many cases, prove to be of little benefit in others. They are essentially methods of applying heat and require, therefore, that they be applied with an appreciation of the concept of *heat dosage*. The physician does not administer several ounces of the tincture of digitalis to his cardiac patient because a few drops have proven to be of value. He appreciates the fact that there is such a thing as an optimum quantity—which if exceeded may do harm and which if diminished may be of little value. This concept of dosage holds equally true for the application of heat, particularly to extremities whose circulation is subnormal.

Landis¹ showed that the capillary pressure is raised to a considerable degree by an elevation in the temperature of the tissues. Thus while in the skin of the finger he obtained, under normal room conditions, a pressure of about thirty-two mm Hg in the arteriolar limb of capillary loops and about twelve mm in the venous limb, he found these values raised to sixty mm. and

forty-five mm at 107.6° F. Since the osmotic pressure of the plasma proteins in man is about twenty-six mm Hg this implies a filtration pressure of edema formation equal to the difference, or some twenty-five to thirty mm of Hg. Presumably this fluid would drain away through the lymphatic system, under normal conditions.

Of interest also is the work of Goldschmidt and Light² who showed that the venosity of venous blood returning from a limb depends upon the balance between the metabolism and rate of the blood flow. Both of these are increased by a rise in temperature. The changes are not parallel. At high temperatures the rate of circulation was increased so greatly that the venous blood contained large amounts of oxygen even though the metabolism was undoubtedly much increased. Bazett and Sriyatta³ demonstrated that when the temperature is elevated not only is there a change in the oxygen saturation of venous blood, but physicochemical factors are brought into play which considerably modify gas tensions by causing the dissociation of oxyhemoglobin and by modifying the acid-base balance and blood pH.

These physiological investigations indicated that while the application of heat produces a vasodilatation and, therefore, an increase of the collateral blood-bed when the normal vascular channels have become partially or completely occluded as a result of disease, it is possible to aggravate the diseased condition by the application of too much heat. Depending upon the degree of pathologic involvement in a given case there is an optimum amount of heat which can be applied.

In 1931 Starr⁴ indicated this to be his experience in the clinical care of individuals suffering from vascular disease of the lower extremities. He determined this optimum temperature by placing the involved extremities in a large water bath equipped with a stirring device and

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 29, 1936

but it is rarely if ever warranted in duodenal ulcer. I can see no point to subjecting a patient to a risk several times higher than is necessary in order to protect him against a possible marginal ulcer, when his chances of being cured by less drastic measures are eighty per cent or more. That, says Rienhoff, is like playing the trump card first. Furthermore, I seriously question whether the incidence of jejunal ulcer is as high as some authors make it out, many of them, I note, make no allowance in their estimates for the cured patients who do not return. Dr Finney considers that resection as a punishment for duodenal ulcer is out of all proportion to the crime, and adds that it just goes to show how tolerant to punishment the human organism is.

Ryle, in concluding his excellent paper on duodenal ulcer, says that the physician's most important contribution to its prophylaxis is the general advice to nervous individuals in an age which has largely lost its old simplicities. His most important contribution to its therapeutics, he continues, is the observation of the entire disease and the qualities of its victims, to achieve a wise balance in the choice of therapeutic methods. Dr Finney hits the nail on the head even more exactly—and incidentally deflates a good many medical and surgical balloons—when he says that after all nothing is followed by such satisfactory even if temporary relief as leaving everything and going fishing.

EDUCATION NEVER ENDS

The new President of the Medical Association of the State of Alabama, Dr Charles Alston Thigpen, of Montgomery, took occasion to remind his medical brethren in his inaugural remarks that the physician who assumes the attitude that his education is complete upon receiving a piece of parchment in the form of a medical diploma will prove both a failure to himself and a menace to the community he pretends to serve. At this point he has, in truth, but taken the first step of his professional education, he must continue a student throughout life, preserving and cultivating an analytical and

intellectual attitude towards all problems presenting in the busy routine of his daily life. He must early learn that the practice of scientific medicine of today compels the physician to so enlarge his horizon and his scope of vision as to embrace not only the sick individual but also the family group and the community as well. The cure of disease cannot and should not be separated from its prevention, and the conscientious physician who views his profession as an integral and important part of society finds himself in position to make lasting contributions to his fellowman, regardless of where his lot may be cast.

District Branch Meetings

The Annual Meetings for 1936 have been arranged on the following schedule:

October 1 Thursday—Fifth District Branch—Rome

October 2 and 3, Friday and Saturday—Fourth District Branch—Plattsburgh

October 7 Wednesday—First District Branch—Morrisania Hospital, New York City

October 15 Thursday—Eighth District Branch—Buffalo

November 19, Thursday—Second District Branch—Garden City

vised by Buerger has been developed by Dr Saunders⁹. In this, the entire bed upon which the patient lies is slowly rotated so that the extremities may be elevated and depressed.

About five years ago it occurred to me that if it were possible to diminish the atmospheric pressure around the lower extremities as the heart's contraction propelled the blood into the peripheral vascular tree, the flow of blood would be encouraged in blood vessels where, because of pathologic involvement, it had become restricted. I planned to time the occurrence of the negative pressure with the increase in systolic pressure in the blood vessels of the extremities. This was to be followed by an application of positive pressure to the leg during the phase of diastole so as to encourage the return flow through the veins. I found that the mechanism required for this purpose would be too intricate and expensive, so I compromised on a small apparatus which permitted me to alternately evacuate and compress the air surrounding the leg, the change being made by a manually-controlled switch. About two years later I became aware of the work of Landis¹⁰ and of Herrmann¹¹. The basic idea I subsequently learned had been referred to by Junod¹² in 1833.

During the past few years various commercial organizations have been manufacturing positive-negative pressure apparatus to be applied to the lower extremities. Most of them follow the principles emphasized by Herrmann,¹³ namely, that the cycle of pressure changes be produced four times per minute, that they be produced gradually, that the pressure vary from -80 to $+20$. Landis¹⁴ advises that the number of cycles be two per minute, that the duration of the negative (partial vacuum phase) be twenty-five seconds and the positive about five seconds, that the changes be produced abruptly, and that the degree of negative pressure vary from -100 to -120 mm Hg and the degree of positive pressure from $+80$ to $+120$ mm Hg.

Varying reports as to the efficacy of this form of treatment have been made by several workers. It appears to be the general opinion that alternate positive and negative pressure therapy is of value in the treatment of some cases of arterio-

sclerosis, particularly where the major involvement is of the larger and medium-sized vessels. If the capacity for distension of the arterioles and capillaries does not exist, but little help may be expected from the use of this measure¹⁵. In the treatment of cases of sudden vascular occlusion due to emboli, Reid and Herrmann,¹³ and Conway¹⁵ have reported satisfactory results, but de Takats¹⁶ reports contrary findings. In view of the spontaneous improvement which occurs occasionally and the possibility of surgical removal of the embolus if the case is seen sufficiently early, the determination of the exact value of positive-negative pressure in this condition is still a matter to be decided. In the treatment of thromboangitis obliterans, the results in general are reported as unsatisfactory, although Herrmann and Reid¹³ in this disease found beneficial effects. Among the reasons for the differences in therapeutic results obtained in the treatment of this condition and that of arteriosclerosis may be the fact that in thromboangitis obliterans the veins as well as the arteries are involved.

A defect in the positive-negative pressure apparatus as it exists today is the fact that compression is made around the leg by the cuff used to seal off the device into which the leg is placed. This pressure must be adequate to maintain the vacuum produced within the device and also the positive pressure. No matter how carefully arranged, the pressure of the cuff does cause some embarrassment to the venous circulation and, also to a lesser extent, the arterial circulation. This is a primary deficiency in the apparatus now available. It may be possible to overcome this objection by placing the entire lower extremity in a device so that the constricting cuff may be made to encircle the lower abdomen and thus remove the pressure upon the vascular channels of the lower extremity.

The diagnosis of peripheral vascular disease has been facilitated by physical means which have been made available in recent years. For usual purposes, the old stand-bys of inspection to observe color changes (a determination improved by the color charts of Sir Thomas Lewis), palpation to determine roughly the coolness or warmth of the extremity, and also to

a heating unit. He found this optimum temperature usually was at the level of about 93.2° to 95° F. At this temperature elevation the cyanosed feet approached the most normal color and the pain became lessened. He heated these patients by placing them in bed and covering their legs with a foot cradle containing heating elements and equipped with a thermostat to maintain the temperature inside of the cradle at the previously determined optimum temperature level. The cradle was kept in operation constantly for twenty-four hours a day. Subsequently Starr⁶ added oxygen to the air in the cradle. The concentration of this gas reached a level of eighty per cent. He used this additional procedure in the treatment of gangrene. He also added calcium chloride placed in pans within the cradle to keep the air dry to cause a dehydration of the gangrenous part.

It is my opinion that, in general, of all the physical measures available for the treatment of peripheral vascular disease, the thermostatically controlled heating hood is the most valuable.

Larger quantities of heating energy such as the conversive heat developed by diathermy and short wave current machines should be cautiously applied. During the initial treatments the energy used should be decidedly less than that used in the treatment of an extremity with intact circulation. Any evidence of harmful effects such as increase in pain or the development of or increase in the cyanosis of the treated part calls for cessation of this form of therapy or a reduction in the quantity of energy used. The diathermy current may be applied in various ways. For example, one electrode may be placed under the lower back and another upon the under surface of the foot, or one electrode may be put on the anterior aspect of the thigh while the other is placed on the calf. The short wave currents may be applied in a similar manner, or by means of a coil encircling the leg. These treatments are usually applied every other day. They are frequently of definite value.

Brown⁷ of the Mayo Clinic has advocated the intravenous injection of typhoid vaccine to produce elevation of body temperature. He considers this

a very useful measure in the treatment of peripheral vascular disease. I have treated cases by means of systemic temperature elevation produced through physical agencies, and the results in most of these cases have been unsatisfactory. One particularly brilliant result was secured in a young man who suffered from thromboangitis obliterans. He was unable to walk a short city block without stopping because of the pain. After a series of eight treatments his condition improved markedly so that he was able to secure a position which required him to remain on his feet and move about for several hours a day. There has been no regression, but, on the contrary, some further improvement in this condition during the past four years. In spite of this dramatic result, my general experience leads me to the conclusion that if heat is to be applied to cases of thromboangitis obliterans, it is best applied by means of the thermostatically controlled heating hood rather than by physically induced fever. In view of the period of initial vasoconstriction after the injection of typhoid vaccine, it appears more logical to use physical means where it is desired to induce the elevation of systemic temperature in the treatment of this condition. Adson⁷ advises that following the intravenous injection of typhoid vaccine, the increase in the skin surface temperature of the big toe should be at least twice as much as that of the systemic temperature to indicate that it would be of value to perform a sympathetic ganglionectomy.

Exercise was advised by Buerger⁸ who developed a series of motions designed to increase the circulation. With the patient lying in the supine position, the extremity is elevated 60 to 90° above the horizontal for the minimum time required to produce ischemia (thirty seconds to three minutes). It is then allowed to hang down over the end of the bed until one minute after the appearance of the reactionary rubor (two to five minutes). The leg is then held in the horizontal position for three to five minutes. These procedures may be repeated for one half hour to one hour.

A new apparatus for the mechanical production of exercises like those ad-

temperature of the big toe. By means of such determinations I have observed that acetyl salicylic acid causes vasodilatation. This drug frequently gives greater relief to the sufferer from pain due to insufficient circulation of the extremities than does morphine. The smoking of tobacco usually causes a drop in the skin surface temperature. Smoking should therefore be strictly forbidden to the individual suffering from peripheral vascular disease, as has been emphasized¹⁹

Alcohol causes a peripheral vasodilatation. The effect of whiskey seems to be more marked than that of wine. Coffee causes a vasoconstriction of the blood vessels of the lower extremities. The great majority of twenty-five normal subjects who ingested two cups of coffee (taken at a temperature of approximately 100° F) showed a lowering of the skin surface temperature of their big toes. No particular change of temperature occurred in these subjects, however, following the ingestion of decaffeinated coffee. The injection of caffeine with sodium benzoate

intramuscularly caused a fall in the skin surface temperature of the toe. This also occurred when the subject took caffeine citrate by mouth.¹⁸ From these observations it would appear advisable to caution the sufferer from peripheral vascular disease against the taking of caffeine. Intravenous administration of hypertonic salt solution causes an elevation in toe temperature. The temperature-increasing influence of hot baths, phototherapy, diathermy, and short wave currents has also been demonstrated.

The objective evidence gained by means of the thermocouple will permit us to evaluate the effects of many other drugs and procedures, so as to enable us to rationalize their application in the treatment of peripheral vascular disease. The development of new physical procedures promises to greatly extend our ability to diagnose and to give physiologic relief to sufferers from peripheral vascular disease.

Discussion

DR. KRISTIAN GOSTA HANSSON, *New York City*—Dr Bierman's paper is a very comprehensive review of our present knowledge of peripheral vascular diseases and their treatment by physical agents.

I agree with Dr Bierman as to the importance of the thermostatically controlled heating hood in these pathologies. I like to emphasize the low grade of temperature and the long period of exposure.

I would like to add a few words about my own experience with pressure-suction machines. I have been interested in this form of treatment for the last two years, and have under my supervision three of these machines, which are occupied all day long. I use the machine devised by Herrmann of Cincinnati with a positive pressure of

twenty mm Hg and a negative pressure of eighty mm Hg, and three cycles per min. Such passive vascular exercises exert a powerful mechanical action on the capillaries and cause the collateral arterial pathways to enlarge slowly. Therefore it becomes evident that we must have a certain amount of elasticity in capillaries and arterioles, and there is a danger of spreading infection and dislodging thrombi by this form of treatment. However, in an elastic capillary bed, and in the absence of infection and thrombophlebitis, these pressure-suction machines offer a valuable addition to therapeutics of peripheral vascular diseases.

Careful clinical history and physical examination, including palpation of peripheral

discover the presence or the absence of pulsations in the dorsalis pedis and posterior tibial arteries are still among the most valuable routine measures.

The Pachon oscillometer which indicates the gross pulsations in the extremity is of definite benefit in the objective determination of changes. It does not, however, furnish an accurate quantitative measure of circulatory efficiency. In a case of aneurysm of the popliteal artery, for example, the oscillometric oscillations showed almost a complete absence of pulsations while other evidences—clinical appearance, ability to walk, thermal reactions—indicated the presence of a highly-developed collateral circulation.

The systemic temperature of the body is maintained within a narrow range in spite of the marked variations in its metabolism and in the temperature of its environment. The body has a delicately attuned thermoregulatory mechanism. This permits it to continuously balance heat loss and heat production. The major mechanism by means of which heat is conserved or lost appears to be the vasoconstrictor and vasodilator apparatus of the blood vessels of the skin of the extremities. The marked fluctuations of temperature in this region can be measured by means of skin surface thermocouples. The area of the skin surface of the big toe is the region which seems to fluctuate the most. Under usual environmental conditions, there is a declining gradient of surface temperature from the torso to the peripheral portions of the extremities.

We can utilize the fluctuations of toe temperature for diagnostic purposes. If the temperature level is threatened by the application of heat to any part of the body such as, for example, by immersing the forearm in hot water at 110° F., the temperature of the skin surface of the big toe is seen to rise to a level approximately that of the level of the surface of the forehead. The skin gradient which normally obtains under ordinarily comfortable environmental conditions becomes obliterated. If there be any occlusive difficulty due to organic changes in blood vessels, this rise does not occur or is much retarded.¹⁷ This may be readily demonstrated by observing the toe temperature of normal subjects with and

without constriction of the leg by means of a cuff which is inflated to a pressure of about sixty mm Hg. The temperature of the toe of the constricted leg will be found to rise but very slightly, while that of the unconstricted leg will rise to a temperature level of the skin surface of the forehead. The temperature of the forehead appears to be relatively stable so that it serves as an excellent criterion for purposes of comparison.

In arteriosclerosis, thromboangitis obliterans, varicose veins, and embolism, the temperature of the skin surface of the toe rises very little, if at all, on immersion of the forearm in hot water. We are thus enabled to differentiate between vessel spasm and organic difficulty. Immersion of the forearm in cold water causes a reduction in the skin surface temperature of the toe unless some organic difficulty be present to prevent it.

When a moderate amount of heat is applied directly to the lower extremities as by means of a hood, the temperature inside of which is maintained at a relatively fixed level by means of a thermostatic mechanism, I have observed that the skin surface temperature of the toe gradually rises to a level a little below that of the temperature of the forehead in the normal subject, it rises quickly and above this level in arteriosclerosis, and slowly and to a point decidedly below this level in varicose veins. In thromboangitis obliterans, the rate and degree of rise resembles that of the normal, inasmuch as there is involvement of both arteries and veins in this disease.¹⁸

The direct application of cold air to the lower extremities causes a rapid fall in skin surface temperature. This response is delayed and diminished in the presence of vascular disease such as arteriosclerosis and thromboangitis obliterans.

During inhalation anesthesia and spinal anesthesia, the temperature of the skin surface of the toe rises in the normal person, but not where there is organic peripheral vascular difficulty. During local anesthesia there normally occurs a rise in the temperature of the skin in the region supplied by the blocked nerves.

The vasodilator or vasoconstrictor influence of food and drug products may be determined in the living subject by observing the changes in the skin surface

temperature of the big toe. By means of such determinations I have observed that acetyl salicylic acid causes vasodilatation. This drug frequently gives greater relief to the sufferer from pain due to insufficient circulation of the extremities than does morphine. The smoking of tobacco usually causes a drop in the skin surface temperature. Smoking should therefore be strictly forbidden to the individual suffering from peripheral vascular disease, as has been emphasized.¹⁹

Alcohol causes a peripheral vasodilatation. The effect of whisky seems to be more marked than that of wine. Coffee causes a vasoconstriction of the blood vessels of the lower extremities. The great majority of twenty-five normal subjects who ingested two cups of coffee (taken at a temperature of approximately 100° F) showed a lowering of the skin surface temperature of their big toes. No particular change of temperature occurred in these subjects, however, following the ingestion of decaffeinated coffee. The injection of caffeine with sodium benzoate

intramuscularly caused a fall in the skin surface temperature of the toe. This also occurred when the subject took caffeine citrate by mouth.¹⁸ From these observations it would appear advisable to caution the sufferer from peripheral vascular disease against the taking of caffeine. Intravenous administration of hypertonic salt solution causes an elevation in toe temperature. The temperature-increasing influence of hot baths, phototherapy, diathermy, and short wave currents has also been demonstrated.

The objective evidence gained by means of the thermocouple will permit us to evaluate the effects of many other drugs and procedures, so as to enable us to rationalize their application in the treatment of peripheral vascular disease. The development of new physical procedures promises to greatly extend our ability to diagnose and to give physiologic relief to sufferers from peripheral vascular disease.

Discussion

DR. KRISTIAN GOSTA HANSSON, *New York City*—Dr Bierman's paper is a very comprehensive review of our present knowledge of peripheral vascular diseases and their treatment by physical agents.

I agree with Dr Bierman as to the importance of the thermostatically controlled heating hood in these pathologies. I like to emphasize the low grade of temperature and the long period of exposure.

I would like to add a few words about my own experience with pressure-suction machines. I have been interested in this form of treatment for the last two years, and have under my supervision three of these machines, which are occupied all day long. I use the machine devised by Herrmann of Cincinnati with a positive pressure of

twenty mm Hg and a negative pressure of eighty mm Hg, and three cycles per min. Such passive vascular exercises exert a powerful mechanical action on the capillaries and cause the collateral arterial pathways to enlarge slowly. Therefore it becomes evident that we must have a certain amount of elasticity in capillaries and arterioles, and there is a danger of spreading infection and dislodging thrombi by this form of treatment. However, in an elastic capillary bed, and in the absence of infection and thrombophlebitis, these pressure-suction machines offer a valuable addition to therapeutics of peripheral vascular diseases.

Careful clinical history and physical examination, including palpation of peripheral

pulses, oscillometric studies, x-ray, and skin temperatures, should precede any treatment

The results so far obtained indicate that

- 1 It is superior to any other treatment in acute peripheral circulatory stasis such as frostbite.
- 2 In arteriosclerosis obliterans about eighty per cent are improved
- 3 In acute vascular occlusion, thrombosis, embolism or operative ligation of arteries, it helps to maintain the collateral circulation and may save an amputation. We have had eleven of these patients with definite benefit to at least nine of them
- 4 In thromboangitis obliterans, it is of value only in early cases
- 5 It is of decided benefit in impaired circulation of polio patients who suffer much in cold weather
- 6 I have also seen favorable results with this treatment in rheumatoid arthritis with skin atrophy

In the pressure-suction apparatus, we have a valuable addition to therapeutics. It is new and will be much abused in its application. Careful clinical observations are therefore necessary. Let me repeat that we must have a capillary bed that is capable of constriction and dilatation, and we should avoid pathologies that might be disseminated through the circulatory system.

DR JOSEPH KOVACS, *New York City*—There are many highlights in Dr Bierman's presentation, but I think the most important one is his conception of *heat dosage*. Heat, like any other medication, overdosed can do lots of harm—especially in peripheral vascular disease. (The circulation in a normal extremity is increased as the local temperature is raised. This increase is caused partly by the increased metabolism of the tissues.) In an extremity affected by organic obliteration of the vessels there is in normal conditions an inadequacy present between the blood supply and tissue need. Application of external heat will only increase the existing disproportion. Raising the temperature will increase the collateral

blood flow slightly, but will surely increase the blood needs of tissues. Pain will be increased and even gangrene may be produced by injudicious application of heat. In obliterative vascular diseases, if any heat is applied, it should not exceed 95° F. I fully agree with Dr Bierman that if heat is applied, the thermostatically controlled heating hood is the most valuable—but in contrast we have found typhoid injections properly administered the most satisfactory form of treatment for thromboangitis obliterans. Initial constriction in the stage of chill is rather a theoretical than practical disadvantage and can be nearly eliminated or reduced by proper dosage. In over 8000 injections given in our vascular clinic we have not seen any untoward effects.

As Dr Hansson discussed the results with negative-positive pressure apparatus, I would like only to mention that we obtained similar if not better results in intermittent claudication with tissue extract injections using 568-T E. Frostbites seem to me the most important indication for negative-positive pressure treatment, and I have seen spectacular improvements. In thromboangitis obliterans the results were unsatisfactory and in many cases treatments have had to be discontinued due to a newly developed plebitis.

I am sorry that Dr Bierman had no time to report his experience of the treatment of spastic vascular disease, as Raynaud's disease.

I will only mention that we experimented with mecholyl iontophoresis in the spastic form of vascular diseases and the results have been very encouraging. Similarly we have very good results with this form of treatment in varicose ulcers. I wish to call your attention to our scientific exhibit on varicose ulcers in the booth of the Vascular clinic of the Post-Graduate hospital where the technic and results of treatment can be seen.

THE FIRST TEN YEARS ARE THE WORST

The Doctors' Symphony Orchestra of Akron, Ohio, ended its first decade with its 61st concert in June. It will open its eleventh season this fall.

Thus a group of physicians and dentists with a recruiting field limited as to the personnel and, during the past five years, with no outside financial support, except donations from a few medical friends, have by their own efforts accomplished what no other group in Akron has been able to do, that is, maintain a symphony orchestra. During its ten years the Orchestra has had the goodwill of the professional musicians and their

Union because it has refused to play on any occasion which would deprive musicians of "pay jobs." In other American cities, Newark, N. J., Seattle, Detroit, etc., doctors orchestras have been formed, but it is to be regretted that they did not last. Only the medical and dental professions of Summit County have succeeded. During its ten years there have been changes in personnel each year and no less than sixty-five members of the two professions have been members of the Orchestra. The strength of the Orchestra at the concert of June 7 was thirty-seven.

RENAL FUNCTION FOLLOWING TRAUMA OF THE KIDNEY

A Clinical and Experimental Study

JOHN H. POWERS, M.D., *Cooperstown*

From the Department of Surgery and the Laboratory for Surgical Research of the Mary Imogene Bassett Hospital

The intelligent treatment of patients with traumatic lesions of the kidney depends upon a knowledge of the degree of function which the organ may be expected to regain when healing is complete. There is an occasional case in which the damage is so extensive and the hemorrhage so severe that immediate operation, preceded by transfusion and other supportive measures, is a necessity and a life-saving procedure. The vast majority of patients, however, do not require such radical and heroic treatment. Hemorrhage from the kidney, pain, tenderness, and spasm may persist for days and be followed by rapid and complete restoration of renal function. Clinical evidence and experimental data to support this statement are herewith presented.

Clinical Reports

CASE 1 A young girl, fifteen years of age, was admitted to the Mary Imogene Bassett Hospital following an automobile accident in which she sustained a blow in the right flank and right lumbar region. Pain and frequency of urination occurred, the urine was not grossly bloody.

Examination showed tenderness throughout the right side of the abdomen, most marked in the flank and costovertebral angle. The temperature, pulse rate, respiratory rate, and blood count were normal. A slight trace of albumin was present in the urine, the sediment contained numerous red cells and a few white cells.

The patient was cystoscoped and both ureters were catheterized. A normal amount of urine was obtained from the left kidney and almost none from the right. One c.c. of phenolsulphonphthalein, containing six mg. of the dye, was injected intravenously, the dye appeared on the left side in two and one-half minutes, none was excreted by the right kidney during a period of eighteen minutes. Following the injection of five c.c. of ten per cent sodium iodide into the right renal pelvis, the patient complained of pain in the flank, and the procedure was discontinued. A right pyelogram revealed a

definite abnormality in the contour of the pelvis and upper portion of the ureter, suggesting either the escape of dye into the parenchyma of the kidney or partial obliteration of the calyces and upper ureter, presumably by clots of blood (Fig 1a).

Conservative treatment was advised and she was discharged to the care of her family doctor.

The patient was readmitted to the hospital five days later because of recurrent pain in the right flank and costovertebral angle, with vomiting. She was again cystoscoped and both ureters were catheterized. A temporary obstruction was encountered on the right side, ten cm. above the ureterovesical junction, beyond which the catheter was eventually passed to the pelvis of the kidney. The urine from the right side was turbid and bloody, from the left, clear and straw-colored, cultures of both were negative. The divided function was repeated, the dye appeared on the right side in two and one-half minutes and eighteen per cent was excreted by this kidney during the subsequent fifteen minutes. A retrograde pyelogram revealed a normal renal pelvis (Fig 1b).

Following cystoscopy the patient was free from pain and a few days later she was referred back to her local physician.

CASE 2 A boy, aged fourteen years, was injured in a sliding accident. He received a blow in the left flank, vomited several hours later, and did not void until the following morning when he passed grossly bloody urine. He complained of constant aching pain in the left flank, aggravated by breathing, coughing, and turning in bed.

During the evening he again voided bloody urine and was referred to the hospital, thirty-six hours after the accident.

The abdomen was uniformly distended, exquisitely tender, and spastic over the entire left side and flank, some tenderness and spasm were present on the right side. The epigastrium was tympanitic and the lower abdomen, dull to percussion.

Roentgenogram of the abdomen with the patient sitting up in bed showed no gas beneath the diaphragm, the stomach was dilated. Five hundred c.c. of urine containing

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 28, 1936

old blood were obtained by catheterization, much gas and 150 c.c. of fluid were withdrawn from the stomach through a small tube passed through the nose.

The temperature was 100.6° F, pulse rate one hundred, and respiratory rate twenty-eight, the leukocytic count was 18,150 with eighty per cent polymorphonuclear neutrophils, the urine was loaded with red cells. Two days later the hemoglobin was fifty-four per cent and the erythrocytic count was 2,250,000.

Tenderness and spasm in the left flank and left side of the abdomen gradually diminished and the temperature and pulse rate subsided to normal on the tenth day. Grossly bloody urine was passed for a total of three weeks. Intravenous pyelograms showed gross deformity of the left renal

sequent fifteen minutes. Retrograde pyelogram showed marked improvement in the topography of the renal pelvis (Fig. 2b). The urine from the left kidney was normal and culture was sterile.

The examination was repeated again in six weeks. Still further improvement in pelvic topography and renal function was apparent (Fig. 2c). The boy was free from symptoms and no tenderness or mass was present in the flank or costolumbar angle. The urine was normal except for a rare red blood cell in the centrifuged sediment.

Comment. The first patient sustained a moderately severe injury of the right kidney, both the functional and anatomical changes in the kidney were transient and recovery was complete. The second pa-

Fig. 1 Retrograde pyelograms, Case 1 (a) Deformity of the renal pelvis and upper portion of the ureter following trauma of moderate severity (b) Prompt return of normal pelvic topography and renal function

pelvis consistent with a traumatic lesion (Fig. 2a). Cystoscopic examination was attempted but the boy was so nervous and apprehensive that the procedure was discontinued.

On the day before his discharge from the hospital (four weeks after the accident) the urine was pale yellow in color, the specific gravity was 1.018, and the reaction, acid, a very slight trace of albumin was present, the sediment contained numerous single and clumped white cells and an occasional red cell per high power field. The P.S.P. test yielded seventy-five per cent in the first hour and five per cent in the second, the N.P.N. was forty-three mg per one hundred c.c. of blood, the hemoglobin was ninety-five per cent and the erythrocytic count was 4,530,000.

Three weeks later the patient was readmitted for cystoscopy which was performed under nitrous oxide and oxygen anesthesia. Phenolsulphonephthalein was injected intravenously, the dye appeared from the left kidney in two and one-quarter minutes and six per cent was excreted during the sub-

sequent fifteen minutes. Retrograde pyelogram showed marked improvement in the topography of the renal pelvis (Fig. 2b). The urine from the left kidney was normal and culture was sterile.

The result of conservative treatment in these two cases, plus the interest aroused by some remarks of Dr. Lowsley before this Section last year prompted the author to undertake the following experimental studies.

Experimental Studies

FIRST SERIES The effect of renal trauma on the function of the single kidney of rabbits previously subjected to unilateral nephrectomy.

Method. Male rabbits weighing between three and three-quarters and four and three-quarters pounds were used. No food or water were given after five o'clock in the afternoon of the day preceding the experiment.

Fig 2. Pyelograms, Case 2 (a) Gross deformity of the renal pelvis following severe trauma, the ureter was not visualized. (b) Retrograde pyelogram 35 days later, the contour of the pelvis was much more normal and the function of the kidney was fair (c) Six weeks later still further improvement in pelvic topography and renal function was apparent.

The normal renal function of the intact animal was first determined as follows

The rabbit was placed in a supine position on the animal board. Blood for determination of the non-protein nitrogen was collected by cardiac puncture. The prepulse was then retracted and a sterile soft rubber catheter, size No 10F, was passed into the bladder. The urine was aspirated with a syringe and put aside for later routine analysis. The bladder was irrigated with tap water until the return was clear, the catheter was clamped and left in place.

One hundred to 150 c.c. of normal saline solution (depending on the size of the rabbit) were given by gastric tube in order to stimulate a satisfactory flow of urine. One c.c. of phenol-sulphonaphthalein, containing six mg of the dye, was then injected into a marginal vein of the ear and the exact time recorded at the completion of the injection. The bladder was aspirated through the catheter every ten minutes during the first hour and at half-hourly intervals during the second hour. At each aspiration, the bladder was irrigated with a fixed amount of tap water in order to wash out all the dye therein contained. Each specimen was alkalized

with sodium hydroxide, diluted to fifty, one hundred, two hundred, or five hundred c.c., depending upon the depth of color, and the amount of dye was computed by comparison with a series of commercially prepared standard solutions.

These studies were repeated until a normal fractional curve and total output were established for each animal. The routine analysis of the urine and determination of the non-protein nitrogen of the blood were similarly checked.

Intravenous pyelograms with skiodan were attempted on several animals according to the method described by Mengert.¹ Every detail of this technic was closely followed yet the renal pelvis were not visualized once in several attempts. Consequently the procedure was discontinued.

Right nephrectomy was performed with sterile surgical technic under basal anesthesia of urethane supplemented by ether. At intervals varying from one week to one month after the immediate convalescence, all

the preoperative studies were repeated and closely checked.

The *left kidney* was then *traumatized*. The organ was exposed retroperitoneally, delivered from the renal fossa, and allowed to lie on the gauze covering the lumbar muscles and skin at the posterior angle of the incision. The anterior surface of the kidney was struck smartly several times with the rounded end of a Wedgewood pestle, about one inch in diameter.

Moderate trauma (four to five blows) caused diffuse subcapsular hemorrhage, capsular tears, and small cortical lacerations on both the anterior and posterior surfaces of the kidney. Severe trauma (eight to nine blows) (Fig 3) frequently produced complete decapsulation, extensive ragged wounds of the parenchyma extending into the renal pelvis, and profuse hemorrhage.

The contused and bleeding organ was replaced and the wound closed in layers with fine silk.

The function of this *single traumatized kidney* was studied daily for four days, again on the sixth, eighth, tenth, and fourteenth postoperative days, at the end of three weeks, and again at the expiration of one month.

Results Six animals were included in this series. Three of them, in which the kidney was subjected to trauma of moderate

CHART I—EFFECT OF RENAL TRAUMA OF MODERATE SEVERITY ON THE ABILITY OF THE KIDNEY TO EXCRETE PHENOLSULFONPHTHALEIN

P.S.P. Test — Total Output in 2 Hours

severity, survived. One of these has been sacrificed for pathological study of the renal tissue, the remaining two are alive and in good health. The detailed studies of each of these two rabbits are presented in Tables I and II. The determinations before and after removal of the right kidney represent the average of two or more observations, those after contusion of the left kidney are single determinations. The effect of trauma on the function of the single kidney as measured by the total excretion of phenolsulphonphthalein, the non-protein nitrogen of the blood, and the specific gravity of the urine are presented graphically for the group in Charts I-III. The effect upon the fractional excretion of the dye during the early posttraumatic period in one animal is charted in Chart IV. These indices of renal function all returned to normal levels within a period of fourteen days after the injury.

CHART II—TEMPORARY NITROGENOUS RETENTION FOLLOWING RENAL TRAUMA

Non-Protein Nitrogen

The three rabbits whose single kidney was severely traumatized died on the second or third day after contusion. The urine was grossly bloody, the specific gravity was low, heavy traces of albumin were present, the output was diminished, and in one instance complete anuria occurred. Either none or minimal amounts of phenolsulphonphthalein were excreted and the non-protein nitrogen of the blood rose rapidly to high levels. The detailed studies of one such animal are presented in Table III.

CHART III—EFFECT OF RENAL TRAUMA ON SPECIFIC GRAVITY OF THE URINE

Conclusion Renal trauma of moderate severity impairs the ability of the kidney to excrete urine of normal concentration, reduces the early elimination of phenolsulphonphthalein, decreases the total excretion of the dye, and causes an abrupt and conspicuous rise in the non-protein nitrogen of the blood. Albumin, red cells, white cells, and casts of various types are found in the urine. The restoration of normal renal function is prompt and complete.

Sudden, severe, and extensive trauma is incompatible with life if the opposite kidney has been removed.

The fatal outcome in the three nephrectomized rabbits whose single kidney was severely traumatized led to the further study of the effect of extensive unilateral renal injury in rabbits with both kidneys intact.

After the immediate posttraumatic period had been safely passed the undamaged kidney was removed, leaving the animal only the severely injured organ for the subsequent maintenance of renal activity.

SECOND SERIES The effect of severe unilateral renal trauma on the renal function of normal rabbits. Subsequent removal of the untraumatized kidney with complete functional recovery of the injured organ.

Method The preliminary studies were similar to those in the first series. The left kidney was then seriously traumatized by eight or nine blows with the pestle. All the studies were repeated on the first, second,

CHART IV—ALTERATIONS IN FRACTIONAL EXCRETION OF PHENOLSULPHONPHTHALEIN DURING EARLY POSTTRAUMATIC PERIOD (RABBIT 31)

fourth, and seventh days after injury. On the eighth day the normal right kidney was removed. The function of the remaining damaged organ was determined at appropriate intervals thereafter.

Results This series of experiments has not yet been completed so that the results cannot be presented as composite curves for the whole group. The detailed studies of one animal are tabulated in Table IV. From a study of this it is apparent that severe trauma of one kidney caused no significant change in the excretion of phenolsulphonphthalein, in the non-protein nitrogen of the blood, or in the specific gravity of the urine. Following removal of the undamaged organ, the impairment of renal function was transient and slight.

Conclusion If severe injury is inflicted

upon one kidney of a normal rabbit, the renal function will be maintained quite satisfactorily by the opposite kidney, with no significant impairment during the immediate convalescent period. If this normal organ is then removed, the traumatized kidney will recover sufficient function to continue the maintenance of renal activity at a normal level thereafter.

The experimental results suggest that severe unilateral renal trauma in man may be treated conservatively (unless immediate operation be necessary to save life from hemorrhage) with the reasonable expectation of good functional recovery in the injured organ.

Summary

Two clinical cases of renal trauma, one moderate and one severe, have been reported. The ability of the injured kidney to excrete phenolsulphonaphthalein and the pyelographic appearance of the renal pelvis returned promptly to normal in the first case. In the second instance the recovery was less rapid but equally satisfactory.

Experimental observations have been

submitted which demonstrate the prompt return of normal function following renal trauma of moderate severity in rabbits with only one kidney. Severe and extensive injury after unilateral nephrectomy is followed by death.

Severe trauma of one kidney, if the opposite organ is intact, produces no significant change in total renal function, measured by the fractional and total excretion of phenolsulphonaphthalein and the non-protein nitrogen of the blood. If the normal kidney is removed after the critical, immediate posttraumatic period is over, the injured organ will recover sufficient function to maintain renal activity at a normal level.

The clinical reports and experimental data suggest that the majority of patients with unilateral renal trauma may be treated conservatively with the expectation that the injured kidney will recover sufficient function to be a useful and serviceable organ.

THE PUBLIC HEALTH CONVENTION IN NEW ORLEANS

More than one hundred separate scientific sessions, with 300 speakers, are listed in the program of the sixty-fifth annual meeting of the American Public Health Association in New Orleans, October 20-23. There are highly specialized programs designed to solve current problems in the fields of administration, nursing, school health work, health education, sanitary engineering, vital statistics, laboratory practice, child hygiene, industrial hygiene, epidemiology. There are programs covering over-lapping interests which involve several groups of specialists who come together in joint meetings for common discussion. There are programs broad enough in scope and of sufficient importance to warrant the attendance of the entire Association in general sessions.

Advances in Public Health is one such General Session. Other General Sessions will deal with diphtheria immunization, mental hygiene, mosquito-borne diseases, and professional education.

A symposium on syphilis is featured. Administrative, epidemiological and laboratory aspects will be presented respectively by Dr. J. N. Baker, State Health Commissioner of Alabama, Dr. George H. Ramsey, Director of the Division of Communicable Diseases, New York State Department of

Health, and Dr. A. H. Sanford of the Mayo Clinic. Discussion will be opened by Dr. Thomas Parran, Surgeon General of the United States Public Health Service.

Other symposia include industrial sanitation, milk and dairy products, infant and maternal mortality, enteric fevers, nutritional problems, registration of births and deaths, care of communicable disease in the home, food poisoning, sanitation of eating utensils, intestinal parasites, school health education, school nursing, business aspects of the health department, and publicity.

More than 2000 public health workers are expected to attend from every state in the Union, from Canada, Cuba, and Mexico.

On the invitation of the Cuban Government and Florida health authorities, the Association will sponsor an all-expense post-convention tour to Havana via Florida by train, motor and steamer. Delegates are invited to join the tour.

The American Public Health Association offers a copy of the program which includes hotel and railroad information, a summary of the post-convention tour and other details concerning the Annual Meeting to those who write to the Association's office, 50 West 50 Street, New York City.

MALIGNANT MELANOTIC TUMORS IN THE NEGRO

ROSS E. HEROLD, M.D., Willard

Clinical Director Willard State Hospital

In spite of the references in the literature to tumors of melanotic origin, little has been said regarding the racial incidence of this condition, and only a very few instances have been reported in which negroes have suffered from malignant melanomas.

Sequeria and Vint¹ state that views on the apparent rarity of malignancy in the African in his native environment must be modified. During a period of eight years 2228 specimens of native tissues were examined at the Native Hospital in Nairobi, and of these 482 were malignant. Of the 482 malignant tumors recognized during this period, 184 were cancers of the skin and adjacent mucus membranes, and fifty-two of these were melanotic in origin. Both sexes were equally represented, and all were adults. The foot was the commonest site, and the majority of the tumors occurred on the plantar surface.

Ewing² mentions the occurrence of melanoma in the negro and suggests the possibility that many cases are overlooked on account of the surrounding dark skin.

Wieting and Hamdi in Constantinople, among a series of 10,000 deeply pigmented oriental people and negroes, including 2,000 patients suffering from ophthalmic disease, recall only six melanotic tumors, two arising from the soles of the feet, one from the gall-bladder, and three from the eye. None of these six patients were very deeply pigmented.

In West African natives Adler and Cummings³ found few cases of malignant neoplasms, although one of the eight cases mentioned, was a melanotic tumor of the foot, with metastases to the inguinal glands.

In the United States, Hazen⁴ reported a case of melanotic tumor, with metastases to the inguinal glands and lungs in a negro, forty-four years of age, following an injury to a mole on the sole of his foot six months previously. Sutton and Mallia⁵ carefully studied a malignant melanotic tumor arising in the toe of a negress, seventy-eight years of age, fol-

lowing an injury which had occurred nine years previously. She died of widespread general metastases. They discuss the rarity of this condition and refer to six additional cases.

Baurer reports two cases, the first a negress, twenty-three years of age, with a history of an injury to her thumb a year previously, and the second a deeply pigmented male, forty years of age, in which the toe was first involved with secondary involvement of the inguinal glands and lungs.

It is difficult to offer any satisfactory explanation as to why malignant pigmented tumors or even benign nevi should be rare in tissue which is normally the site of large amounts of pigment. Matas believes that pigment production is a normal function of the negro skin and that it is under a well-developed physiological control, while in the white race, pigment is limited to a few scattered areas, and its physiological control is poorly developed.

Fig 1 Metastatic tumors in right arm

W H, colored, was admitted to the Willard State Hospital on October 27, 1919, where a diagnosis of manic depressive psychosis of the manic type was made, and died there after a continuous residence on June 29, 1935. The condition which resulted in his death, began in October 1934, as closely as can be determined. At that time, he developed a gangrenous condition of the index finger of his right hand, and an amputation was performed. At the time, a deeply pigmented tumor mass was noticed on the dorsal surface of the hand, just posterior to the site of the amputation. Very shortly afterwards, a similar growth appeared on the roof of his mouth which had attained the size of a walnut, it was removed January 25, 1935. The specimen was examined in the State Laboratory, where a

diagnosis of melanotic sarcoma was made. Within the next three months, many metastatic tumor masses appeared in the skin, more particularly of the right arm and shoulder (Fig 1). During the same period, many neurological signs developed, indicating involvement of the nervous system. He also developed symptoms relative to his respiratory system.

An autopsy was performed which showed

Fig 2 Axillary lymph gland

Fig 3 Metastasis in right lung

Fig 4 Section of liver showing large metastatic nodule

Fig 5 Low power microphotograph of section of cerebral cortex showing punctate involvement with melanotic tumor

marked metastatic involvement of the brain, liver, lungs, and spleen as well as numerous nodules on the body surface. Some of these masses were very small while others had attained the size of a lemon. The axillary

lymph glands were extensively involved. Fig 2 shows one of these. The tumors were all deeply pigmented, and many of them contained large amounts of dark colored gelatinous material. The lungs (Fig 3) showed many deeply pigmented tumor masses of varying size, as did the liver (Fig 4 and Fig 7) and kidneys.

The cerebral cortex (Fig 5 and 6)

Fig 6 High power microphotograph of Fig 5

Fig 8 Left cerebral hemisphere showing large metastasis near the posterior end of the lateral ventricle

Fig 7 Microphotograph of melanotic nodule in liver showing almost complete absence of liver tissue

Fig 9 Microphotograph of wall of a blood vessel adjacent to a tumor nodule showing infiltration of blood vessel wall with melanin

showed many masses varying in size from a pinhead to one cm. in diameter. There was an area of pigmentation and softening near the posterior portion of the left lateral ventricle (Fig. 8). Just anterior to the fissure of Rolando, on the right cerebral hemisphere, was a nodule about $1\frac{1}{2}$ cm. in diameter as well as innumerable smaller masses.

In general the same type of pathology was found throughout all the tissues showing tumor involvement. There was a variable amount of melanin pigment in all the masses examined microscopically, although some of the cells showed little or no pigmentation. One specimen showed invasion of the walls of a blood vessel (Fig. 9) by tumor cells which would indicate the possibility of spread through the vascular tree.

Comparatively few cases of melanotic malignancy in negroes have been reported. In most cases, trauma has a definite bearing

on the development and spread of the tumor. In this case, the amputation, no doubt, had some effect, increasing the spread of the melanotic tumor masses with resulting metastasis in practically every organ in the body. Metastases occur very rapidly, with death resulting in a comparatively short time.

I wish to express my appreciation to the Staff of the Psychiatric Institute, and to the Laboratory of the State Department of Health for their help in making the diagnosis and preparing photographs of the pathological specimens.

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B. LIBER, M.D., D.P.H., New York City

Editorial Note: Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine.

Blight

He makes his own diagnosis and gives the etiology too.

"I am depressed. I don't care about anything. Nothing interests me. I see people around me who struggle and fight, who are full of ambition, who run hither and thither. I understand them, but I don't envy them. I feel I should not be as I am. I am only thirty and, as you see, I am not sick, that is I am physically well—tall, broad shouldered. I am not working and am not looking for work, although I am skilled. Satisfied to live with my old mother who is a widow and has a small pension. She ought to chase me out of the house, but she does not. She owns the house, by the way, and there are lots of things to fix in it and I can do it, but I keep on postponing it and never get around to do anything. The house needs painting, but it looks to me like an immense job that I don't want to tackle it, although it's nothing. Sometimes I am much better. Then I am alive, like one of those hibernating animals when they awake in spring. I read, I work, I fix mother's car, I go to see a show or a friend. I go back to a girl I know, but who is otherwise indifferent to me. There is fun in everything, watching the waves at the beach in moonlight, looking at the crowds in the street,

driving a car. But that doesn't last long. For instance, just now I wouldn't touch the auto. I am afraid. You see, it's all due to my father. Yes, it's his fault. He crushed me. He was awfully severe and had a bad temper. We all crawled into our corners when he came home. He used bad words against my mother and threw the dishes around or broke the chairs. If we dared to move we were beaten up. When I was fifteen I was already taller than he and something stirred in me. But my mother called me into another room and said, 'No nonsense, we need peace, if I can stand it you can too and what would you do, have two crazy people in here instead of one?' And so I laid down low and let the storm pass. Evenings, when friends and schoolmates had a good time, I was not supposed to leave my desk. I had to study hard, to make good. And my head was filled with funny ideas about life, things that I see now in a different light, but I cannot help it any more. It's too late. I was a little improved after my father's death, but the whole condition came back later. In one of my good spells I loved a girl. I mean I loved her really and she loved me. But as soon as we had sexual relations the old morality with which my parents had

stuffed me returned. The girl couldn't be good, I said to myself, if she gave in—and I left her. She was the saddest thing on earth, but within a year she got married and I lost her. In my livelier moments I still care for her and I know she is still fond of me. But what's the use? My other sisters and brothers were smarter than I. They couldn't stand my father's iron rule. They all ran away from him and for a long time

he didn't know where they had gone or what they were doing. Each time this happened he fumed and snorted like a wild beast and he was wilder to those remaining and especially to my mother. But I stayed and this is the result."

Several talks proved that his case was not desperate and that a great improvement was possible.

Light and Shadow

Woman of forty-seven, two children, youngest fifteen

For three years "one happy day followed by one unhappy day—literally a day and a day, but more shadow than light," she says.

Wishes to die, to commit suicide, but never tried.

"Some day I'll fall down from a high building, or I'll get run over, or I'll get drowned. I keep on asking myself whether it's worth to carry on."

"Yes, I did plan to get rid of life. As a matter of fact I'm making some plans all the time. I think of death only."

Speaks well and much and seems to enjoy her unhappiness. Indeed, allows no one else to say anything, as she never stops.

"Has no enemies, friends only." Lives at home with her family.

Does her work—but on the bad days with great effort.

Although her husband is "nice to her,"

she is not satisfied with him—and there lies the cause of her trouble. While she does not blame him for her condition, she does not praise him either and criticizes him severely in a general way.

Physically normal. Sex intercourse normal and satisfactory. Menses still regular and unchanged. Family history is negative.

Patient is sociable when feeling well, has "no dreams."

It is a case of mental depression, of pessimism, which, if the situation will not become worse, will remain as it is. A transition case, where conversations can help much. The cause must be revealed to her and she must be shown that, if she chooses to continue to live with her husband, she should accept her plight. The real remedy lies in some interest and activity which would take her often away from her household interests.

A WET BLANKET FOR THE COLD SHOWER

Those hardy souls who seek to demonstrate their intrepidity by taking a cold shower in the morning before rushing off to work, place their systems under "a tremendous strain" which in some cases may lead to great harm and even premature death, according to a warning sounded at the fifteenth annual convention of the American Congress of Physical Therapy.

Dr Hans J Behrend of the Hospital for Joint Diseases told the 1,000 doctors at the gathering at the Waldorf-Astoria Hotel that he was opposed to any one, even those in robust health, taking a cold shower at any time. He prescribed the lukewarm shower, with the water temperature about the same as that of the body, as the ideal bath. The best time to bathe, he added, was just before retiring at night.

"Those in robust health and with good circulation can overcome the strain engendered by the cold shower," Dr Behrend said, "but those less fortunate, particularly weak, anemic and older people, may suffer serious damages as a result of it. Colds, feebleness and fatigue are some of the harmful effects of the cold shower habit."

"In the case of the person in perfect health, the cold shower tends to stimulate the muscles and to refresh a person suffering from fatigue. Although I would not advise any one to take a cold shower, those who have made a habit of it may lessen the possible strain on themselves by regulating the flow of water so that the shower shifts from lukewarm to hot, or from hot to cold, slowly and gradually."

Dr Eliot Bishop of the Kings County Medical Society says that something must be done to reduce the cost of bringing babies into the world. Unless that is brought about,

he believes, the cost will have to be met by loans advanced by the State or parents will wait till they are middle aged before they can afford to have children.

Anent the Quality of Medical Care

Professor Henry Sigerist once said that the society it serves influences the type and character of medical care that society receives. Sigerist has since become one of the proponents of socialized medicine. What he said, nevertheless, based as it was on studies of the trends in medical practice during the changing epochs of history, is essentially true.

If the strong individualists who compose our great middle class are passing, as Louis Corey believes, then this country, instead of consisting of individual farmers, store-keepers, manufacturers et al,—this class will be replaced by a great army of job-holders. The liberal professions of law and medicine, too, having almost no private clientele upon which to draw—because there would be so few independent persons in the society of the allegedly ensuing epoch—will perforce have to conform to the pattern of the society about them, and they also would become part of the great job-holding public. Only in this way can one conceive that the thetic statement of Sigerist can find substantiation.

Naturally it would follow, were Corey's opinion to come true—an opinion with which we do not find ourselves in accord—that we would have a less vital, a less virile, and a less potent middle class. Likewise we should have medical men of

lesser caliber and poorer type. The job-hunting and job-holding groups are nowhere conceded the equal of those who take life as they find it and carve out for themselves from their environment, and from the circumstances it presents, careers and achievements and worldly goods to better their living standards.

During the various phases of historical times, if we trace the trend of youth toward occupations we find that when interesting and adventurous careers were closed to most walks of life except in the Church, brilliant youth gravitated to the Church. When adventure and army life held lure under the Napoleonic influence, the brightest and best sought a Marshal's baton in an army career. When, at the end of the nineteenth century, industrial development offered fame and fortune as rewards for initiative and courage to those who essayed these careers, intellectually adventurous youth gravitated to these fields. This period also saw the rapid and astounding developments in medicine, because here too, individualistic endeavor brought adequate rewards, and the medical career was both interesting and attractive. The same brilliant types were attracted to medicine as to the industrial fields of endeavor. In all these activities, men were their own masters. They were

much encouraged by, but were not controlled by government agencies. In education the stress was on the development of the individual doctor, and none on anything else. Medical schools and colleges could successfully raise their standards of requirements for admission, and of curricula. To these schools came some of the best among our youth, and the institutions of learning could exercise their power of selecting the best of these. From this the public benefited by receiving a better grade of medical service.

The country's educators should ponder on the problem that will confront them if the efforts of the protagonists of compulsory health insurance have their way, and the proposed form of delivering medical care to our people is thoughtlessly adopted.

What type of youth would be attracted to a medical career? After a difficult medical course of four years, and the necessary preparatory one, then the arduous postgraduate internship—to be qualified for what? A job, with a fixed income, with a definite number of assigned patients who, to follow the custom set in England, are not thoroughly examined even if there were time allowed to do it, fixed hours of work, perhaps a paid vacation, and at the end—a pension. A job-holder's career! A government employee with all that this implies!

Obviously, will it not be quite a different type of man than those who have won high renown and have given American medicine the high place it holds today?

Will not the stress in medical education also have to change? Will it not be necessary to train American medical officials rather than American doctors? We see a similar change in a trend in the field of nursing. Formerly all student nurses were educated alike, now there is a distinct change in stress toward educating nursing administrators. Those who will actually handle the sick are, apparently, slated to have less arduous curricula to cover. Since the financial income will be greater among the medical

administrators of the system than among those of the rank and file who handle the sick, medical education will soon change to meet the demand of those who will seek careers, not as physicians to the sick, but as part of the controlling bureaucracy set apart and over the physicians. The colleges will give two types of education to meet the changed conditions. Reasoned our further, it will become necessary to lower standards (as was done in Russia) to attract sufficient numbers to meet the needs of the so-called lower branches of the medical system. Lower standards, reduced entrance requirements, and a totally different type of individual will be found taking up a medical career. And all this is proposed "for the betterment of mankind"!

We, who are opposed to compulsory health insurance, call to the attention of our educators these thoughts, for we are deeply concerned with the *quality* of medical care our community will receive. For it we desire only the best quality of medical care obtainable, delivered by a man or woman of the highest type.

The medical educators of our country have here a responsibility that they must continue to carry. In the discussions of the pros and cons of compulsory health insurance, obviously it is not an economic problem nor is it wholly a sociological question. It is a problem with which the educators of our youth are also concerned. Medical education must be planned to the end that we may maintain what we have laboriously won—a lower death rate, and a lower morbidity rate than any country where compulsory health insurance is in force, and a level of preventive medicine not equalled in any of the countries of Europe whose example we are so blithely being urged to follow.

Bonanza or Bubble?

"Gold Mine or Gold Brick"? This question has inspired the American Institute for Economic Research to a study of the influence of the Social Security Act

on the average American citizen. From the point of view of those who will actually receive benefits, monies paid in may yield "a profit of 600% on a government guaranteed investment * * * Any ordinary investment which promised such great returns would be regarded with suspicion by every experienced investor." To counterbalance this, " * * of course, many individuals may be forced to make sacrifices without being so handsomely rewarded * * *"

Addressing the average citizen, the Institute for Economic Research warns, "The Social Security taxes will leave you less to spend for the things you need and want." Under it, "you may have to pay, not one, but several thousand dollars. Part of this will be taken from every paycheck which you will receive for many years to come. The remainder you will pay in the form of higher prices for food, clothing, car, shoes, and everything else you buy * * * It may be that you will pay a portion of the cost in the form of higher prices, but will never get one cent's worth of benefit from the Act."

Without impugning the motives or aims of the Social Security Act in any way, grave doubts have been expressed both as to its constitutionality and its ability to achieve its purpose. To the medical profession all this is particularly interesting as a foretaste of what may be expected if compulsory health insurance is added to existing legislation.

The picture of unrequited payments which the Institute for Economic Research paints in connection with unemployment and old age insurance is equally true for compulsory health insurance. The inevitable rise in taxes and living costs engendered by the present law would be augmented by obligatory prepayment for sickness. Compulsory health insurance would intensify and multiply the bureaucratic evils inherent in the existing social security legislation.

The welfare workers and politicians who put through the general Social Se-

curity Act are already complaining that the promised benefits are not complete without health insurance. They will attempt to bring the latter to pass even though the constitutionality of the former is still in doubt. It must be remembered that, " * * until the Supreme Court speaks, the Act will be the law of the land, and taxes will be imposed upon employer and employee, even if pensions and unemployment benefits are never paid." Ordinary common sense dictates that any decision on compulsory health insurance be postponed until the constitutional status of the existing laws is defined and their efficacy observed.

Well-Founded Confidence

Writing for the September issue of *Medical Economics*, Dr. Floyd S. Winslow, President of the Medical Society of the State of New York, defends popular judgment on non-scientific phases of professional practice. Technical questions are no fit gauge of lay opinion and should not be submitted to it. In many of the social and economic aspects of medical care, however, the public has a stake second only to that of the physician, and it is increasingly assuming the right to help settle the problems with which it is directly or indirectly concerned.

The profession should welcome and encourage intelligent popular participation in the solution of the economic and sociological problems associated with medical care. Far from constituting a danger or encumbrance, informed public opinion is the best ally the doctor can have. It is up to physicians, acting individually as well as in organized groups, to see that the laity is fully and accurately informed on matters in which it has a justifiable interest.

The blunders of democracy have given rise, in some minds, to an unwarranted contempt for popular discretion. Compared to the vices of many monarchies and most dictatorships, the errors of democratic judgment appear slight in-

deed and relatively easy to overcome. Naturally full and free education is indispensable to the formulation of sound opinions, and in subjects related to medical practice the physician should recognize his obligation to furnish correct, complete information in terms comprehensible to his listeners.

The purchaser of medical care, like the buyer of any other service or commodity, holds definite views on his purchase. While a layman is rarely able to appraise professional judgment or skill, quoting Dr Winslow, " * * * there have arisen a number of questions related to the work of our profession, which are not essentially scientific or therapeutic, and on which a lay person with a trained mind may be equipped to form a sound opinion * * * Now I am free to say that I think there are certain exceptions to the rule that the public may be trusted. But there are even more serious objections to assuming that they cannot be * * * "

The profession has its choice between enlisting lay support by a frank exposition of the non-scientific ramifications of medicine or alienating public opinion by a hierarchic refusal to discuss any aspect of practice with the laity. In the recent nation-wide high school debates on compulsory health insurance popular judgment was vindicated by the strong case built up for the negative in most of the contests. You can't fool all of the people all of the time—and it is the doctor's job to see that the public has authentic information from which to formulate sound opinions on medical questions.

The New York Academy of Medicine's Graduate Fortnight

Nine years ago, the New York Academy of Medicine inaugurated the first of its series of organized lectures and clinics devoted to the study of certain phases of medical problems. The purpose of this yearly graduate fortnight is to present to the profession the accumulated knowledge on a given topic, prepared

and delivered by authorities in the respective fields of medicine.

This year's Fortnight, which commences on October 19, deals with trauma, occupational diseases, and hazards. Every conceivable aspect of these topics will be covered in the evening lectures at the Academy. The afternoons are to be devoted to clinics and demonstrations of traumatic medicine and surgery. The profession is invited to attend, and detailed information can be obtained by writing to the New York Academy of Medicine. In view of the popularity of the subject to be presented, a large attendance is expected and it is urged that the general admission ticket be sent for well in advance.

Acromegaly and Follicular Hormone

The role of the endocrines in the bodily functions is an important one. A great deal of knowledge has been accumulated during the past few years to add greater weight to the earlier assumptions of the part played by the glands of internal secretion. Not only have the specific physiological functions been established to a great extent, but the information gleaned has been put to practical therapeutic use.

In addition to the individual activity of the various hormones it has been known that their action is more or less interdependent. Some of the hormones possess activating properties on the secretions of other glands while some are distinctly inhibitory. It is in this connection that Kirklin and Wilder¹ studied clinically the effect of follicular hormone on cases of acromegaly. In eight cases wherein this hormone was administered favorable results were obtained as far as the amelioration of symptoms was concerned. The severe headaches were relieved. The visual fields improved, in some instances returning to within normal limits. Some patients noted a decrease in the puffiness of the soft parts and a

¹ Kirklin and Wilder. *Proc. Staff Meet. Mayo Clinic*, 11:121, 1936.

decrease in the amount of perspiration, particularly at night

The investigators have undertaken this study to determine whether the follicular hormone exerts an inhibitory action on the somatotrophic activity of the pituitary gland in cases of acromegaly. They themselves do not intend their report to be interpreted as outlining a new type of therapy for acromegaly. Their clinical results, however, should tend to stimulate further investigation utilizing this type of treatment.

CURRENT COMMENT

"I SOMETIMES QUESTION whether the present tendency to depend so much on memorizing knowledge gives a sound basis of education for the future. Knowledge is static, wisdom is active and moves knowledge making it effective. As I think back on my own classmates in college, I am impressed with the fact that many of them who had fine memories and stood at the heads of their classes in some way in the after years missed acquiring wisdom and did not come up to our expectations. Some students can fill their minds with any given subject, book, chapter, and page, and can regurgitate this knowledge at examination and thereby win class leadership. Such memorizing of knowledge has not necessarily relation to wisdom. After all, the best the college can do is to give the students breadth of knowledge, not necessarily depth of knowledge."—Among the statements made at the 1936 graduation of Notre Dame University by Dr. W. J. Mayo, and quoted in the September 1936 *Supplement* to the *Saint Louis County Medical Society Bulletin*.

"IT WILL BE A SORRY VICTORY for the public if it is ever misled into action that will compel physicians and medical societies to turn aside from their tested traditions and devote their main attention to economic problems. There has been far greater progress in preventive medicine in this country than in any nation in which medical care has been dominated by political and economic interests"—R. G. Leland, M.D.

"IN THIS DAY OF MODERN witch-burning, when freedom of thought has been exiled from many lands which were once its home, it is the part of Harvard and America to stand for the freedom of the human mind and to carry the torch of truth

The truth is great and will prevail. For centuries that grand old saying has been a rock of support for persecuted men.

But it depends on men's tolerance, self-restraint and devotion to freedom, not only for themselves but also for others, whether the truth will prevail through free research, free discussion, and the free intercourse of civilized men, or will prevail only after suppression and suffering—when none cares whether it prevails or not"—President Roosevelt, speaking at the Harvard Tercentenary at Cambridge.

"WE ARE TO BLAME! Only the Doctor of Medicine himself knows what constitutes proper care. Unless the Doctor of Medicine is willing to disseminate this knowledge to laymen, either in groups or to them as his individual patients, the public cannot be expected to know * * * He has a message for the people. A message that must be given. This message is not simply one of a medical nature. Today it goes far beyond that. He must protect a commonwealth against insidious legislation that tends to break down a protection to the health and welfare of the people—a protection that has taken centuries to create. * * *

The greatest task before Medicine today is the proper dissemination of knowledge, dissemination of the truth to the public * * * As a duty to the people, the doctor should learn to talk about his science. Unless he does this the public cannot be blamed for not understanding * * * To successfully protect the public against the countless "isms" that now confuse it, takes a united voice of Doctors of Medicine. A voice that will be heard not only before large gatherings but in every possible individual contact with the public."—The above quotations are taken from an excellent editorial in the *Los Angeles Medical Society Bulletin*.

"* * * AN UNDERSTANDING of medical economics would not precipitate a tyro into a flourishing practice immediately upon graduation. It would, however, enable him to recognize and evaluate forces that retard his economic progress and to weigh doctrines urged upon him in the light of past experience and ultimate consequences. Above all it would teach him the value of organized activity in which the individual is a militant participant instead of an inert part."—*Saint Louis Medical Society Bulletin*.

"IF WE ARE TO MAKE cheapness the hallmark of medicine, then would we return our people to the dark ages when life itself was cheap, for no less than life itself is involved in medical service. As you so well know,

the common cold within hours can be pneumonia, the common fracture can result in a disability for life reducing earnings by a half, diabetes can be lived with or, improperly treated, a cause of too early death, improper diagnosis can mean a life from cancer or prolonged periods of invalidism from any of many causes. When you abandon present standards for fixed sum payments, you enter upon a principle in the operation of which the physician profits most from performing the minimum service—a practice wherein the man who pays hard-earned money for months and years may find the institution that took his payments non-existent when he calls upon it in his time of need”—J G Crownhart in the *Milwaukee Medical Times*

“THE PUBLIC IS A very incompetent judge of your skill and knowledge, but it gives its confidence most readily to those who stand well with their professional brethren, whom they call upon when they themselves or their families are sick, whom they choose to honorable offices, whose writings and teachings they hold in esteem. A man may be much valued by the profession and yet have defects which prevent his becoming a favorite practitioner, but no popularity can be depended upon as permanent which is not sanctioned by the judgment of professional experts, and with these you will always stand on your substantial merits”—The *Saint Louis County Medical Society Bulletin* has chosen the above from the writings of Oliver Wendell Holmes for its issue of September 4, 1936

THE GENEVA ZONE

It should always be a matter of much interest to the entire Medical Profession when one of its members distinguishes himself by a valuable contribution to the sum total of human happiness and welfare, even though, or perhaps especially, when it is of a non-medical character. When such is the case the contribution takes on somewhat the nature of the soldier's bravery “outside the line of duty” for which special awards exist.

A case in point is the service of a French physician Dr G Este' de Metz, who has organized and is laboring at expanding a most laudable humanitarian movement. This is the “Geneva Zone” idea. In substance, the plan is to establish all over the world in properly chosen locations, distinctly neutral areas, where in time of, or in the event of,

war, the aged, the infirm, children, pregnant mothers and others who because of physical handicaps are entitled to civilization's special consideration, may be completely protected from the inhuman ravages of war. These areas or zones are to be administered by properly qualified persons, entirely free of political, religious or other potentially combatant control.

If the idea, even to that extent, spreads and is successful, says *American Medicine*, it is a great humanitarian movement entitled to respect and support from all right-minded people. If, eventually, it transcends the bounds already set for it, it may lead the way to real world peace—to making the entire world an enormous Geneva Zone where all may be protected from the brutal and selfish aims of war.

TOO INDIVIDUALISTIC!

A criticism heard against the medical profession is that the doctor is too individualistic. That is of necessity true remarks the *Detroit Medical News*. A chemist, a physicist, and a mathematician can prophesy the resultant of given elements, forces or factors when combined. Exact science is exact because of this capacity to foretell.

In medicine the certainty of foretelling does not exist. A biological organism has

the capacity of growth and senescence, of mental development and deterioration. When to these is added the third variable of a sense of ethics, the diagnosis and prognosis makes of each “case” a major problem in the practitioner's art.

It is the degree in which the doctor possesses the ability to treat a patient as an individual that characterizes his qualifications.

AMERICAN HEROES OF SCIENCE

At Hamburg, Germany, recently, forty American radiologists and roentgenologists were named among 165 heroes of science who sacrificed their lives in medical research. The names are chiseled on a sandstone memorial in front of the Roentgen

Institute of St. George's Hospital. The honored Americans include F H Baetjer, Baltimore, W I Dodd, Philadelphia, E Fleischmann, San Francisco, R M Machlett and E W Caldwell, New York, W C Engelhoff and R Friedlaender, Chicago.

A Layman Inquires

New York City

To the Editors

"Time to make everything snug, and prepare to 'ride it out'" concluded the leading editorial in the September 1 issue of your JOURNAL. If this period of quiescence which your editor senses, if this silence on the part of the proponents of State Medicine is indeed an ominous one and a lull preceding a "storm"—then this correspondent seriously wonders whether or not the organized profession is going to heed the "storm-warning" and rally from its unorganized apathy, utilize well these "windless" days and truly prepare to "ride it out"? Will it not be a little too late when the "wind" of propaganda is upon it with doubtlessly renewed vigor for the profession then to formulate an effective counter-program?

In the past the organized profession has silently and sincerely trudged along, healing the sick, counseling its members and adhering to its ethics. Then came the blast from the proponents of socialized medicine for this country. Your journals, nearly every one, answered with intense rebuttals, a sense of outrage bursting forth from every line, and from the profession came a stream of well-timed and fact-laden retorts to the propagandists. *To the propagandists*—and therein perhaps lies another weakness. When the germs of state medicine were sown in this country, when the "wind" of the propagandists was released, the germs were not only scattered on the soil of the profession but were subtly planted in the gullible loam of the laity, and the "wind" hummed an entrancing tune in its ears.

But your keen rebuttals, your revealing facts and apt analogies concerning the standards of medical care here and abroad did not and do not reach it,—and laity, your patients!

The proponents of State Medicine realize that their two most fertile fields of activity consist of the laity which has thus far only heard one side of the question (their side), and of the post-depression and younger medical men who are under economic duress. You, through your journals and excellent society machinery have only perhaps definitely reached the latter. The former as yet goes unprotected, untaught and scarcely warned against the vicious diatribes of the

proponents of State Medicine. What will be your next move—how are you going to prepare to "ride it out"?

Very sincerely yours,

NAME OMITTED UPON REQUEST

An Ex-Coroner Disagrees

15 Cayuga St.
Seneca Falls, N Y

To the Editor

In the September 1, 1936, issue of the N Y STATE JOURNAL OF MEDICINE, the first sixteen pages of the Scientific portion were devoted to an article, "The Teaching of Forensic Medicine", written by Dr. Harrison S. Martland of Newark, N J. As the entire magazine consists of 83 pages, it is evident that you considered Dr. Martland's article of great importance as almost 20% of the reading space for the month was allotted to it. That there is a need in the Medical profession for more knowledge on the subject of medical jurisprudence and medical legal medicine, is a point well brought out and demonstrated in the article mentioned. Dr. Martland is a resident of New Jersey and is familiar with the workings of the New Jersey laws but this knowledge does not, however, qualify him entirely to speak for New York State or other states to which this familiarity does not extend. As a Coroner, with twelve years' experience in up-state New York, I resent very strongly the conclusion on page 1195 that "the position of Coroner is usually held by an individual whose incompetence is matched only by his venality", for personally, I have never seen a dishonest coroner or any attempt at grafting by any incumbent of the Office of Coroner. With regard to the abolition of the coroner, with his "blunders" and "damnable inquests", as they are styled by Dr. Martland, it is in my opinion very doubtful, if the public could be served any better by the exchange of the coroner for a medical examiner outside of the large centers of population. In New York State there are at present 96 coroners, of which the large majority are physicians. These coroners are apportioned in the various counties according to the density of population, and are educated physicians in active practice. They are County officials,

the common cold within hours can be pneumonia, the common fracture can result in a disability for life reducing earnings by a half, diabetes can be lived with or, improperly treated, a cause of too early death, improper diagnosis can mean a life from cancer or prolonged periods of invalidism from any of many causes. When you abandon present standards for fixed sum payments, you enter upon a principle in the operation of which the physician profits most from performing the minimum service—a practice wherein the man who pays hard-earned money for months and years may find the institution that took his payments non-existent when he calls upon it in his time of need.”—J. G. Crownhart in the *Milwaukee Medical Times*

AMERICAN HEROES OF SCIENCE

At Hamburg, Germany, recently, forty American radiologists and roentgenologists were named among 165 heroes of science who sacrificed their lives in medical research. The names are chiseled on a sandstone memorial in front of the Roentgen

Institute of St. George's Hospital. The honored Americans include F. H. Baetjer, Baltimore, W. I. Dodd, Philadelphia, E. Fleischmann, San Francisco, R. M. Machlett and E. W. Caldwell, New York, W. C. Engelhoff and R. Friedlaender, Chicago.

locate. In Arthur Than's "Ein systematischer Überblick über die gesamte deutsche Sozialversicherung in Tabellenform," published in 1931 by the Leipziger Buchdruckerei AG Leipzig C 1, Tauchaer Strasse 19-21 (p 8) it is stated that the number of active employees and officials in the compulsory insurance societies is about 32,000. The Berlin Correspondent of the *J.A.M.A.*, (103 1463, 1934) states "The administration of the Krankenkassen requires the services of 34,000 persons. There are about two administration officials to each one thousand members. The number of panel physicians is about 32,000." In England no record is available to show how many are concerned with insurance administration. Neither do the

governmental reports state how many are employed.

From this it seems that the editorial statement "Lastly, and this is perhaps most important—the lay personnel exceeds the medical personnel in ratios from three to five or more, * * *" is not an accurate nor a correct statement of fact, and we are glad to make this public correction of our error.

On the other hand, however, the implication of the statement is correct, and we stand by it. We meant to imply that the panel system, and its lay control boards create a large class group in the body politic, interested in their jobs, and the pay-roll from which they live. Why should they anywhere seek to abolish themselves?—*Editor*

POSTGRADUATE LECTURE COURSES

Conducted by the Committee on Public Health and Medical Education
Medical Society of the State of New York

A postgraduate course of lectures has been arranged for the Wayne County Medical Society by the Committee on Public Health and Medical Education of the State Society. This course of lectures is being given at the County Courthouse in Lyons, N. Y., on Thursdays in October, at 4 00 P. M.

The first lecture on Pneumonia, September 24, by Dr. Russell L. Cecil, was part of a program which the State Medical Society has been carrying on for the past year, in the hopes of reducing the mortality from this disease. Already significant results have followed from this campaign. Dr. Cecil is the author of a text-book on medicine which is now used in most of the medical colleges of the country. He has had a wide experience in the treatment of pneumonia, being one of the first physicians to become interested in the serum treatment of the disease.

There are several different types of the germ which causes pneumonia, and a serum has been perfected for only certain of these types. It is essential to determine the type of the diseases before beginning the use of

the serum. A rapid method for determining these types has been perfected, and was demonstrated at this meeting by Dr. O. W. H. Mitchell, Professor of Bacteriology at the College of Medicine of Syracuse University, who spoke on the Bacteriology of Pneumonia.

The speakers and subjects of the various further lectures are as follows:

October 1 Dr. Ralph G. Stillman
Significance of Laboratory Tests and Methods

October 8 Dr. Edward Livingston
General Aspects of Abdominal Surgical Diagnosis

October 15 Dr. William Goldring
Physiology of Kidney Diseases

October 22 Dr. Robert T. Frank
Practical Endocrinology

The lecturers in this course are prominent medical teachers, all of whom have given special attention to the subjects which they will discuss.

October 15 Dr. William Goldring
Physiology of Kidney Diseases

October 22 Dr. Robert T. Frank
Practical Endocrinology

The lecturers in this course are prominent medical teachers, all of whom have given special attention to the subjects which they will discuss.

The first lecture, one of practical importance to every physician, was delivered on September 24 by Dr. Russell L. Cecil.

All physicians, whether or not they are members of the State Society, are invited to the lectures.

A postgraduate course of lectures has been arranged for the Cayuga County Medical Society by the Committee on Public Health and Medical Education of the State Medical Society. This course of lectures is being given at the Auburn City Hospital in Auburn, on Thursday evenings in October at 8.30 P. M.

The speakers and subjects of the various lectures are as follows:

October 1 Dr. Ralph G. Stillman
Significance of Laboratory Tests and Methods

October 8 Dr. Edward M. Livingston
General Aspects of Abdominal Surgical Diagnosis

with power to use the funds of the County to investigate crime, with the power of subpoena of witnesses, the power of removal of bodies for examination to such places as may be deemed proper, the power to order and employ a physician to examine the body, and report the cause of death, and the power to employ one or more physicians to perform an autopsy, if this be necessary, to discover the cause of death. They, also, have the power to hold Inquests in suitable cases, but do not impanel Coroners' Juries. Inquests are held at such times and places as the Coroner may designate and are presided over by the Coroner who usually requests the District Attorney of the County to conduct the questioning of witnesses who are under oath. The legal procedure for employing the Coroner in New York State is, that in cases of sudden death from any cause, the local Health Officer is to be notified. He may or may not in his judgment turn the case over to the Coroner for investigation. When the Coroner has ascertained the cause of death from a physician who has examined the body, with or without autopsy, he is ready for the inquest, if he believes one to be necessary. After the inquest, if he is convinced that a crime has been committed and by whom, he issues a warrant for the arrest of the guilty person, to be held for examination before a Criminal Tribunal. Thereafter, the case goes through the channels of criminal procedure with the District Attorney as public prosecutor. All this proceeds in an orderly manner and is checked each year by a written report to the County Board of Supervisors, which goes over the Coroner's bill and the items of valuables found on dead bodies and subjects them to a careful scrutiny, and audit. Dr Martland exaggerates the difficulties in establishing the cause of death. In my twelve years' service, I found the cause of death so obvious in the vast majority of cases that any physician would be able to diagnose it on sight. The autopsies in the remaining number cleared up the cases completely so that not one single case required the elaborate pussy footing and detective work that Dr Martland seems to consider requisite for the Coroner or the medical examiner. In the examination of unknown bodies, it has always been possible in my experience to ascertain, sooner or later, their identity and to get into communication with their relatives or friends. The substitution of a full time "Medical Examiner" for the Coroners now working in this County would mean that a full time Pathologist would have to be employed, who is an expert Toxicologist. His salary alone would be about five times, at least, what the

four Coroners combined cost the County at the present time, and he might have, possibly, one case a year where his expert knowledge would be necessary. With County laboratories operating in the vicinity, the Coroners have no difficulty in obtaining chemical analyses of body fluids or visceral contents, which are entirely satisfactory.

In closing, would say that the unjust abuse of the Coroners without the support of reliable facts does no good in attempting their displacement, even when aided by somewhat feeble profanity, for at present the ancient and honorable Coroner system is working quite satisfactorily and very economically in New York State.

As a constructive reply to such unjust criticism, an Organization of New York State Coroners, to protect themselves against such unwarrantable attacks, would be a logical and not an impossible result.

FREDERICK W LESTER, M.D.,
Ex Coroner, Seneca County, State of New York

Editorial Questioned by Dr I S Falk

49th Floor
49 Wall St.
New York City

To the Editor

In the JOURNAL for September 1, 1936, there appears on page 1258 an editorial which includes the following assertion "Lastly, and this is perhaps most important—the lay personnel exceeds the medical personnel in ratios from three to five or more."

This assertion would constitute an interesting fact—whatever its real meaning or significance—if it is true. I have some familiarity with the original literature on health insurance in Europe but do not recognize that the assertion quoted above bears any easily recognized relation to the facts with which I am acquainted. I shall therefore appreciate it if you will refer me to the original sources of evidence upon which this assertion rests. In this request for *original sources*, I do not of course refer to any similar assertions or to what "everybody knows," however frequently repeated, but to the basic or underlying evidence.

Very truly yours, I S FALK

September 11, 1936

Note There are no available statistics, except for Germany that we have been able to

locate. In Arthur Than's "Ein systematischer Überblick über die gesamte deutsche Sozialversicherung in Tabellenform," published in 1931 by the Leipziger Buchdruckerei AG Leipzig C 1, Tauchaer Strasse 19-21 (p 8) it is stated that the number of active employees and officials in the compulsory insurance societies is about 32,000. PROCEEDINGS OF THE EXECUTIVE COMMITTEE

September 10

Information concerning a new movement called the Doctors' Club—Residences was filed for reference without action. Physicians in this State and also throughout the country have received letters from an Organization Committee which seeks contributions to launch this effort to set up, on a nation-wide basis, homes for superannuated, impoverished physicians. Investigations, instigated by the Secretary through one member and through the Better Business Bureau of New York, indicate that the objective is sound, that the effort is bona-fide, that the individuals concerned are reputable. It should be noted that in New York State this would parallel the Physicians' Home, Inc. which has the sympathetic approval of the State Society.

A question, brought to the attention of the Committee by Dr. K. Winfield Ney of New York, of possible recognition for income tax deduction purposes of charitable work by physicians in hospitals and dispensaries, was referred to the Committee on Economics for full study and report.

Following a suggestion by Dr. C. Ward Crampton of New York, the Committee requested the Committee on Public Health and Medical Education to set up a Sub-Committee on Cancer.

It was brought to the attention of the Committee that two employees of the Yorkshire Indemnity Company now carrying our malpractice insurance under the group plan, were recently convicted of accepting bribes in connection with a fraudulent accident claim. It was noted that both cases are now on appeal. The Executive Committee recorded its opinion that even if the convictions should stand, the situation as regards the integrity of the Yorkshire Indemnity Company is similar to that of a bank whose employee may have absconded with a depositor's funds. Therefore, the Secretary was empowered to advise any inquiring member that, in the opinion of the Executive Committee, he can safely insure or continue to insure with the Yorkshire Indemnity Company under the group plan.

The Committee on Public Health and Medical Education reported the formation of the following sub-committees which were approved:

Pneumonia Control

Russell L. Cecil, *Chairman*, New York City
Oliver W. H. Mitchell, Syracuse
Clayton W. Greene, Buffalo
Peter Irving, New York City

Maternal Welfare

James K. Quigley, *Chairman*, Rochester
Martin B. Tinker, Ithaca
Oliver W. H. Mitchell, Syracuse

Child Hygiene

Edw. J. Wynkoop, *Chairman*, Syracuse
Leo F. Schiff, Plattsburg
Oliver W. H. Mitchell, Syracuse

Nursing Education

Clayton W. Greene, *Chairman*, Buffalo
Oliver W. H. Mitchell, Syracuse
Russell L. Cecil, New York City
Martin B. Tinker, Ithaca

Cancer Control

Edw. G. Whipple, *Chairman*, Rochester
Martin B. Tinker, Ithaca
Oliver W. H. Mitchell, Syracuse

In connection with the study that has been made by the Committee on Economics of hospital customs (distinction between "medical care" and "hospital care") the President was empowered to appoint a special committee with himself as chairman to confer with the State Hospital Association. It is hoped in this way to iron out matters that have been the subject of recent debate between hospitals and the profession.

Information came from the Committee on Workmen's Compensation that agreement had been completed with the Compensation Rating Board as to arbitration procedures.

It was noted that the Commissioner of Labor has not as yet promulgated a fee schedule for the rest of the State outside of the Metropolitan area. The Secretary was directed to advise the Commissioner that the Executive Committee favors the Metropolitan schedule for the rest of the State *without reduction*.

The Workmen's Compensation Committee's stand indicated in the following paragraph was definitely approved, even though litigation may ensue:

The question now arises whether this Committee shall pursue the course (which it thinks best and proper and in accordance with the law) of refusing [rather advising County Boards to refuse] to qualify a physician who is employed by a lay or corporate owned X-ray laboratory and shall refuse also to recommend the licensing of such lay or corporate owned X-ray laboratory. In this event we shall be required to defend our action in the courts. We believe that this portion of the amended Workmen's Compensation Act which was introduced by interested parties as an amendment at the very last moment against our advice is unconstitutional in that it attempts to condone what under the Medical Practise Act is clearly a violation of the Educational Law of this State. Whether the amended Workmen's Compensation Act supersedes in this respect the Educational Law is a question to be determined by the courts.

Officers were appointed for the Physical Therapy Session: Dr. Madge C. L. McGuinness of New York, *Chairman*; Dr. Harold J. Harris of Westport, *Secretary*.

COMMITTEE ON WORKMEN'S COMPENSATION

The Workmen's Compensation Act was amended by the Legislature in 1935 primarily to remove abuses that had crept into the medical care of injured workmen. There is good reason to believe that the amended Act has already brought about a change for the better. A larger number of competent and ethical physicians have been drawn into this work under the free choice principle, and injured workmen have more confidence now under the care of their own doctors that not only will they be properly treated, but that their rights to proper compensation will be protected. It should be the aim of every physician to improve his knowledge in the field of industrial injuries and diseases. It is the purpose of organized medicine to provide every opportunity for the practitioner of medicine to become more familiar with the latest methods of practice in the field of industrial medicine. Important as are the legal and administrative aspects surrounding the care of patients injured while at work, the prime consideration of the physicians should be to provide the highest type of medical care and to restore the patient to his former employment *as soon as possible*. There is every reason to believe that under the free choice principle, the large number of efficient and ethical practitioners who have registered under the amended Act will, under the fee schedule promulgated by the Commissioner, bring down the cost of medical care. It is not the

cost of big operations that increases the total cost of medical care in industrial medicine. It is the overtreating and improper care of minor accidents resulting in complications and in increased disability that in the aggregate raise the cost inordinately.

During the month of October the New York Academy of Medicine is devoting a Fortnight to the subject of traumatic occupational diseases and hazards.

On Monday night, October 26, the Medical Society of the County of New York has arranged an interesting program on the Workmen's Compensation Law. At this time the Hon. Bernard L. Shientag, Justice of the Supreme Court, and former Industrial Commissioner, will speak on the History of the Workmen's Compensation Law and the Lessons it holds for the future. The Hon. Meier Steinbrink, Justice of the Supreme Court, will speak on "The medical witness."

The program of the Graduate Fortnight is especially recommended to all physicians. Numerous clinics are to be held in many of the hospitals of the city, and a varied clinical program of interest to practicing physicians, designed to put them in actual contact with experts in this field, is afforded. Physicians are urged to take advantage of this great opportunity to refresh themselves in this timely and important branch of medicine.

The Silicosis Bill, recently signed by Governor Lehman, (Chapter 887, Laws of 1936) contains an amendment to the Compensation Act which is of interest to physicians of the State of New York. Section 70 of this act reads as follows:

S 70. Special medical examiners. The Industrial Commissioner shall divide the state into five districts and in each district may appoint two or more special medical examiners who shall be licensed physicians in good professional standing, each of whom shall have had, at the time of his appointment, and immediately prior thereto, at least five years of practice in the diagnosis, care and treatment of pulmonary diseases. Such examiners shall be employed on a per diem basis as the exigencies of the work may require. Fees of examiners shall be fixed by the industrial commissioner within the limits of the appropriation therefor. Each position of special medical examiner provided herein shall be in the exempt class of civil service.

Whenever a claim is made under this article and an examination of the claimant by an impartial physician is desired by any party in interest, the industrial commissioner shall order such medical examiners to make the necessary

medical and x-ray examination of the claimant in an effort to obtain the medical facts in an impartial manner.

For the purposes of adjudication under this chapter, the industrial board shall adopt rules of practice and procedure and shall prescribe methods and standards under which physical examinations, x-rays and other studies shall be conducted.

The five districts referred to above are the compensation districts of the State, namely, New York, Albany, Buffalo, Rochester, and Syracuse.

The Industrial Commissioner, in accordance with this act, is now engaged in the selection of personnel for these posts. Those physicians who have the necessary qualifications and desire to be considered should communicate with Elmer F. Andrews, Industrial Commissioner, State Office Building, 80 Centre Street, New York City.

In view of the fact that appointments are to be made within the next few weeks, interested physicians are urged to act promptly.

DAVID J. KALISKI,
Chairman

DISTRICT BRANCHES

The thirtieth annual meeting of the Sixth District Branch was held at Ithaca on September 17, in the theater of the Willard Straight Hall at Cornell University. Attendance reached about 150.

At the morning session Dr William A Brumfield of the State Department of Health described the Syphilis Program of the Department which is now under way. Dr John C M Brust of Syracuse gave a practical review of "Diagnosis and Treatment of Anal Abscess and Fistula." Dr Stafford L Warren and Dr Charles M Carpenter of Rochester presented colored movies, demonstrating their new experimental work with thermic treatment of gonorrheal infections.

In the afternoon President Winslow made a stirring address on "The Doctor's Obligation." Dr David J Kaliski, Director of the Workmen's Compensation Committee, described procedures for arbitration by the County Boards. He also deplored the apparent intention of the Commissioner of

Labor to set up a fee schedule for the rest of the State outside of the Metropolitan area on a basis lower than the Metropolitan area. On motion duly seconded and carried it was decided that the Sixth District Branch advise the Commissioner that it favors promulgation of the same schedule *without reduction* for the rest of the State as the Metropolitan area.

Secretary Irving expressed the desire of the secretarial office to have closer information of County Society problems.

Dr John K. Deegan, in charge of the new Biggs Memorial Hospital, described with the help of a model, the physical plant, and discussed the policies of administration and medical service of the Hospital.

Dr Chevalier L Jackson of Philadelphia gave a clinical presentation of the ways in which a bronchoscope can be used in diseases of the lungs. He stressed the point that the "bronchoscope is only a speculum" and his slides and diagrams gave a vivid picture of the accomplishments resulting from its use.

Third District Branch

The thirtieth annual meeting of the Third District Branch was held in Albany on September 22. Dr Raymond F Kircher, President of the Albany County Medical Society, welcomed 150 members.

In the morning Dr David J Kaliski, Chairman, Workmen's Compensation Committee of the State Society, detailed procedures for arbitration by County Compensation Boards. In a full discussion of the delay in promulgation by the Commissioner of Labor of a fee schedule for the rest of the State outside of the Metropolitan area (for which a schedule has already been set up) it was brought out that the Committee has recommended to the Commissioner use of the Metropolitan area schedule *without reductions* that have been suggested by interested groups other than the physicians. The House of Delegates took this stand, the Compensation Committee has pushed it, the Executive Committee has so advised the Commissioner.

Dr D M Brumfiel of Saranac Lake gave an illuminating presentation of "Diagnosis and Significance of Silicosis." He indicated clearly that two things are required to make a diagnosis—a characteristic x-ray pattern and a history of sufficient exposure.

President Winslow described the activities of the State Society now under way. Secretary Irving asked the help of County Soci-

ties for the secretarial office and for the JOURNAL, both of which play a considerable part in effecting action, and offered active help to County Societies in their problems.

At the afternoon session Dr Edward S Godfrey, Commissioner of the State Department of Health, spoke of plans to use the recently assigned \$500,000 federal fund for promotion of Department work throughout the State. He described a change in the type of clinics in connection with prenatal work and child welfare to make these educational for the public and for the profession. He emphasized his desire to work hand in hand with the profession in this and other features of Department work.

Dr Herbert M Bergamini of New York City gave an excellent presentation of "Fundamentals in the Treatment of Fractures."

Dr John J Rainey of Troy spoke to the title of "A Review of the Nasal Accessory Sinuses."

The following Officers were elected for the next two years: President Bertram W Gifford, M D, Saugerties. 1st Vice-President Lyle B Honeyford, D M, Catskill. 2nd Vice-President Arthur M Dickinson, M D, Albany. Secretary William M Rapp, M D, Catskill. Treasurer Ernest E Billings, M D, Kingston.

Fourth District Branch

The scientific program of the thirtieth annual meeting of the Fourth District Branch of the Medical Society of the State of New

York will be held at the State Normal School, Plattsburgh, October 2 and 3. The program will be as follows:

OCTOBER 2, 2 30 P M

"Treatment of Burns," Lyman Allen, M D, Burlington, Vermont

"Some Remarks on Hormones," James B Collip, M D, Montreal

"Mid-Childhood Hip Joint Disease," Edward K. Cravener, M D, Schenectady

Election of officers

7 00 P M

Dinner at Hotel Cumberland

Address by Floyd S Winslow, M D

Fifth District Branch

The scientific program of the thirtieth annual meeting of the Fifth District Branch of the Medical Society of the State of New York will be held at the Rome State School, Rome, October 1

OCTOBER 1, 10 00 A M

Address of Welcome, President, Oneida County Society or Dr Bernstein, Supt, Rome State School

"Public Relations at Rome State School" Marjorie S Brulle, Social Worker

"Institutional Treatment, Medical," Leonora L Greteman, M D, Asst. Physician

"Vocational Treatment for Mental Defec-

tives," Robert A York, Vocational Director

"Reminiscences," John B Wheeler, M D, Burlington, Vermont (Harvard 1878)

OCTOBER 3, 9 30 A M

"Pulmonary Response to Inhaled Dust," Arthur J Norwald, M D, Saranac Lake.

"Recognition of Early Congestive Heart Failure and Treatment," Lewis M Hurxthal M D, Boston, Mass

"Hyperthyroidism in Children," George E Beilby, M D, and John C McClintock, M D, Albany

Addresses by Officers of the State Medical Society

Luncheon

1 30 P M

"Surgical Aspects of Peptic Ulcer," Donald Guthrie, M D, Sayre, Pa

"Cardio-Vascular Syphilis," Edwin P Maynard, M D, Brooklyn

First District Branch

The scientific program of the thirtieth annual meeting of the First District Branch of the Medical Society of the State of New York will be held at the Morrisania City Hospital, 168 St. at Gerard Ave., New York City, October 7

9 A M

"Operations for Complete Prolapse of Uterus," Harry Aranow, M D, F A C S, New York City

"General Surgery," George E Milani, M D, New York City

"Urological Surgery," Terry M Townsend, M D, F A C S, New York City

"Current Pediatric Cases," Louis H Barnberg, M D, New York City

"Unique Methods of Tonsillectomy," Clarence M. Smith, M D, F A C S, New York City

"Pathological Demonstrations," William Aronson, M D, New York City

"Interesting Neuropsychiatric Cases," S Philip Goodhart, M D, New York City

"Interesting Eye Cases," Thomas Hayes Curtin, M D, New York City

Luncheon

AFTERNOON SESSION

"State Society Problems," Floyd Winslow, M D, F A C S, President, Medical Society of the State of New York, Rochester

"The Journal," Peter Irving, M D, F A C P, Secretary, Medical Society of the State of New York, New York City

"Compensation Medicine," David J Kaliski, M D, Director, Workmen's Compensation Bureau, Medical Society of the State of New York, New York City

"Neurosurgery," Sidney W Gross, M D, New York City

"Demonstration of Unusual X-ray Films," Samuel F Weitzner, M D, New York City

"Surgical Diabetes," Frederick W Williams, M D, and Thomas J O'Kane, M D, F A C S, New York City

"Radiation Therapy of Neoplastic Diseases," William Harris, M D, and Samuel Richman, M D, New York City

"Cardiac Clinic," Edward R. Flood, M D, New York City

"Treatment of Fracture of Femur," William Klein, M D, F A C S, New York City

"Grand Rounds and Demonstrations in Obstetrics," Harry Aranow, M D, F A C S, New York City

comments from the various counties as to any other program which they would like to see developed, which will put the doctor in proper relationship with the State agency for the provision for care of these people

THE CHAIRMAN Dr Elliott, I am going to carry that a little further. If these county society secretaries write to you asking help for each individual county, are you prepared to give them advice as to how to carry on the arrangements, how to make the arrangements in that county?

DR. ELLIOTT We shall undertake to give them the advice according to our current information. That brings a very important point to my mind. Two counties, in discussing with their executive secretaries last night, have become quite controversial with their local welfare offices and have undertaken to make certain adjustments of their relationship. Not that the State Committee or any organization of the State Society would try to dictate to any county how things should be done, but that we may coordinate the various efforts of the various counties and not have some county step overboard and give the State official agencies a justification for something that is unacceptable to the State at large, I think that whenever these issues come up between a local county and their local agency or the State agency that some notice of it, some information about what is going on, should be given to Dr Hambrook's Committee on Public Relations and to the Economics Committee for the economic aspect of it and perhaps even to Dr Farmer's committee on the health angle. I think your State Committee Chairman should be constantly informed of your local county committee relationships whenever they become at all involved with the public agencies

THE CHAIRMAN This fits right into the keynote of action I tried to establish this year. I think it would be well if this group could arrange some definite mechanism. It comes to my mind, Dr Elliott, that you have appointed the members of your Committee as more or less consultants for different areas in the State. That is correct, isn't it?

DR. ELLIOTT Yes

THE CHAIRMAN Why not have the county secretaries, instead of writing to you immediately, approach the sectional member of your Committee? He will be primed to help them, will he not?

DR. ELLIOTT I think so

THE CHAIRMAN To iron the thing out in quick fashion?

DR. ELLIOTT Very definitely, and he will come to the Committee's files if he lacks any detailed information himself

THE CHAIRMAN Well, he probably knows already, does he not, from your long discussions?

DR. ELLIOTT He has, I feel, very complete information at the present moment

DR. NELMS Because of the confusion that now exists and will probably exist in the minds of many doctors regarding the difference between compulsory and voluntary health insur-

ance, I think we might ask Dr Elliott to enlarge a little on the policy that the Executive Committee adopted last spring. As you know, the Legislative Committee has been instructed to support in the Legislature this principle of voluntary health insurance. Dr Elliott has made a study of this problem and I think he is better able than any other man in the State to point out the essential difference between these two types of insurance and why it is possible for the Medical Society of the State of New York to apparently reverse itself in the position that it has taken through the years and to favor some type of controlled voluntary health insurance.

DR. ELLIOTT An architect can't stand at the top and build down, and that is what compulsory health insurance does. Compulsory health insurance starts with a Commission and a Commissioner and then district branches and then local branches and so on down. Contrasted with that, indemnity insurance must be built on the ground. As it has been discussed with the State Insurance Commission, the idea is to limit each activity to a smaller locality, grouping of one small community, of one industrial plant, so that the people who receive the benefits and who pay the freight will be close to and acquainted with the people who are responsible for administration. That makes it possible for indemnity insurance to be operated so that less than five per cent will be spent on administration and more than ninety-five per cent will go for actual benefits to the people who are seeking relief. Contrasted with which, compulsory health insurance is essentially a bureaucracy scheme. It is a job-building political ideal, originally conceived as such in Germany and enlarged upon in every other country, minimized politically perhaps in England at the present moment, but nevertheless still the administrative expense is large. The people who are in authority are remote from the people who are getting the service and the red tape in between leads to serious delay, complications, and dissatisfaction on the part of both the people who are doctored and the doctors who render the care. That, in a nutshell, is the substance of it.

One has worked efficiently, and that is at Brattleboro, Vermont. I have been there several times, dropped into a grocery store and bought something, this, that or the other. They don't know who I am or what it is about, I draw the clerk or whoever I meet into conversation and I haven't found one person up there that didn't speak well of their plan. I met two or three of the doctors and they didn't know who I was. They liked it, and by all the comment that I can get from everyone abroad there is the very opposite opinion prevailing on the foreign scheme. In one instance satisfaction on the part of all the people participating, on the other, dissatisfaction and criticism from all angles.

Lt. DR. NATALE Could Dr Elliott tell us the Brattleboro plan in a few words?

DR. ELLIOTT It was established by the Thomas Thompson fund donation of about \$1500 and it was established first with nursing care. A single person for \$3, a married

couple, I think, for \$3 50, and fifty cents for each child, can be protected against economic disaster due to the demands or needs for nursing care. Then they established the hospital benefit association and boiling that down to this, for \$14 50 a man wife, and two children may have insurance which will protect them for any expense above \$21 in any one sickness episode for one year. Now, is that clear? In other words, if the wife is taken sick in February and must go to the hospital, she must pay the first \$21, after which the insurance picks up the load and carries the next \$300. Perhaps in April the husband is taken sick and he must pay the first \$21. Now, just exactly what the initial payment must be, I am not prepared to say for New York State as a whole or any community, but the principle is this, that the individual demanding a benefit under his insurance is inhibited from making unnecessary demands for trivial, and inconsequential complaints, and the Insurance is relieved of the great cost of administering the details of this borderline zone between health and disease. Anyone that pays out \$20 or \$30, whatever you want to make it, as an initial expense, you may be reasonably sure, is sick, and by that simple expedient they have eliminated all of the malingering and all of the troubles that have beset all the foreign systems.

The fee schedule paid in Brattleboro, Vermont, is better than our workmen's compensation fee schedule, designed by the doctors, and about a year and a half ago by their voluntary action as a group, several of the fees were lowered as a proper adjustment of fees to the conditions which prevailed at the time.

THE CHAIRMAN I want to ask this question, Dr. Elliott, if you will make it plain. Who actually determines whether the doctor's bill in the case is proper or not, and is there any trouble over such a matter?

DR. ELLIOTT None whatever. The arrangement as to what the individual should pay is a question between the patient and the doctor. The patient makes his own choice of doctors, makes his own arrangements, pays his bill, and submits that bill to the Insurance. They make the standard deduction and send him a check for the balance. In other words, it is an indemnity. The Insurance doesn't contract to provide the individual with a doctor. It contracts to reimburse the individual for an expense which sickness and disease have occasioned.

THE CHAIRMAN In other words, eliminating thereby one of the great objections to all insurance things in the past?

DR. ELLIOTT Right.

DR. KENNY Who administers the insurance, Doctor?

DR. ELLIOTT A Miss Wells is the whole works in Brattleboro. She has a parlor up on the second floor, a telephone, and a little desk. This is a town of about five or six thousand with three or four thousand surrounding and this lady by the community gossip route knows everything. I was there visiting her one day and the telephone rang. "Oh yes, Mrs. So-and-so, yes, I know you were

in the hospital. You paid \$42 50? I will send you your check this afternoon." That is the whole administration. Didn't have to send out an investigator. Didn't have to fill in a lot of forms. She knew. And so it goes in the community. Anyone that is seriously sick, the whole community knows about it and this little lady runs the thing. I think the Brattleboro expense of administration has amounted to less than one per cent over a period of more than eleven years.

That is the philosophy of this indemnity insurance as your State Insurance Commission sees it. Keep it within small groups who by linkage of acquaintance and community knowledge of each other can control any abuse which might otherwise develop. As Mr. Bradley, the trustee of the Thomas Thompson Fund, says, "If it is in the group and each one is going to dig into his own pocket to pay the bill, they keep an eye on it, but if we write insurance in Vermont and the insurance office is in Manhattan, the fellow who checks up on it says, 'That insurance company is rich. Let's give Bill a little more,'" and he says that is where your trouble starts in ordinary insurance.

DR. DI NATALE Who appoints this lady?

DR. ELLIOTT The Association of Insurance. It is a mutual association.

Remarks by Dr. Mitchell, Committee on Public Health and Medical Education. I regret very much that Dr. Farmer can't be here, because he is so familiar with the activities of this Committee, having had charge of it, I think, now for about ten years. His recent illness has made it impossible for him to attend, but he is feeling very much better and wanted to be remembered to every one of you.

In the working of the Public Health Committee we feel that one of the chief obstacles to making the work more efficient is some lack of cooperation of the county organization. Of course, there is a great difference in our county set-ups. Some of them have a large membership and some of them small. In some of the county societies one committee would handle a great many activities and in some of the other county societies there are not so many, and naturally the load is bound to vary and also the interest of the individual. On the whole, however, we feel that we have received excellent cooperation from the county societies.

Perhaps one factor that enters into this lack of efficiency at times is the changing of the officers of the county societies. Of course, I think the time will eventually come when a secretary will hold office longer than is common in many of the units. I appreciate why it is that no one doctor cares to be secretary for a long period of time. It is quite a job, and while he gets a great deal of experience, of course, he also gets many complaints and other things to bother him, and he would just as soon somebody else were to handle it for a while. However, as the years have gone by I think we see a tendency to keep the secretaries in office longer, just the same as we see the tendency to keep the officers of our State Medical Society on committees longer, that they understand. I don't know just what

reward is going to come to a man who continues as secretary for a number of years. Perhaps they will make him president if he lives long enough, some great honor like that.

The chief activities of the Public Health Committee you are quite familiar with. At the present time aside from the postgraduate education they center around these four features—pneumonia control, maternal welfare, child hygiene, and cancer control. I don't know of any activity which has gone along better than the work in pneumonia control during the last year. That was evidenced in many ways. In the first place by the members of the Committee itself, the appointment of a sub-committee under the leadership of Dr Cecil, then the establishment of cooperation and a special pneumonia committee appointed by the Commissioner of Health of the State, and bringing together the many activities which may be in operation for pneumonia control, that is, such things as widespread publicity carried on by our own publicity bureau, and the committee in charge of that, the widespread publicity and educational work of the State Health Department, and then the production of the serum and its distribution by the State Health Department, and the establishment of laboratories available for typing and many similar activities, and particularly successful we feel was the education program carried out throughout the State under the direct supervision of our Committee. So that in practically all counties, as you know, from the detailed report which was published in the *JOURNAL*, practically the entire State, each county society, had or more meetings on the subject of pneumonia. We feel that an excellent start has been made and as well as we can determine from discussing it with the various organizations and individuals, a really much better program will be carried out this coming winter.

We hope that each county society will again devote one program to the question of pneumonia and if you are not in a position to arrange that program yourself, we will welcome a letter from you or, if you so desire, a personal visit from one of the Committee to talk over the question of pneumonia and go over that program. Don't think because you held one meeting this last year that you have done all that is expected to be done on the pneumonia problem, because it is constantly expanding. More work has been carried out, intensive work in the last two or three years, and in all likelihood we can do a great deal more from now on in the diagnosis and treatment of pneumonia than we have ever done before.

The maternal welfare program is under the direct supervision of Dr Quigley of Rochester who is the chairman of the sub-committee, and we also hope that every county society will have its committee on maternal welfare or commission. (Some call them commissions and some committees.) Be active from now on. If you have not organized a maternal welfare committee, we suggest that you do that immediately. Any questions which arise in your minds about the program that you want to carry out or about what is being done else-

where, either in different counties in this State or in other states, write to Dr Quigley at Rochester and he will supply you with the information. Again, if you feel that some member of the committee, particularly Dr Quigley or some members of his committee or the advisors, could help you, don't hesitate to make that request known and as soon as possible one of the physicians will meet with you.

The child hygiene program has not been formulated as yet. A meeting will be held very soon and a number of consultants will meet with the sub-committee to discuss the proposed activities of a child hygiene program in New York State. Of course, as all of you realize, there are a number of organizations involved in a child hygiene program, particularly through our government agencies, and we want to have a very clear understanding as to what activities are to be carried out and what is expected of them. In charge of that program for this year is a member of the Public Health Committee, in charge of the sub-committee is Dr Wynkoop of Syracuse and so from now on any questions or any information that you care to ask about the child hygiene program should be directed either to Dr Farmer or to Dr Wynkoop. Perhaps it is just as well with most of these things if you would direct your communication to Dr Farmer, then he can forward it to the sub-committee chairman or to the particular doctor that he thinks could best handle that.

On the question of cancer control the program for that is in the making, and here again a number of different organizations are concerned. Just how extensive that program will be, nobody can say at the present time, and the sub-committee of the Public Health Committee has as its chairman Dr Ed Whipple of Rochester. Meetings by the chairman, Dr Whipple, and the members of his sub-committee will be held with the representatives, of the government, the State Health Department, and other organizations concerned with cancer control, such as the American Society for Control of Cancer, etc. So we must await further information about the details of these programs.

Now, of course, the Committee on Public Health and Medical Education can't solve all these problems by itself and we will naturally be working with the other committees of the Society. As fast as programs are accepted or the outlines of programs, the details are accepted by the Committee. They will be submitted to Dr Irving and those in charge of the publications, and such reports will appear in the *JOURNAL*.

I regret again to say that Dr Farmer cannot be here and give you more details, but essentially these matters are the chief activities which concern that Committee at the present time.

THE CHAIRMAN. In asking for discussion, I would like to make one comment on my own. This method of sub-committees for different things that one committee takes care of, has proven most satisfactory and successful with this particular committee.

MR. NEFF, Nassau County. I have been

asked to seek some advice on our present checkmate on the pneumonia campaign. We have succeeded in getting plenty of laboratory facilities for patients in the hospital, but we have not been able to make any arrangements for the indigent outpatient. The fee in the private hospital for typing is five dollars. This is out of reach of the borderline economic group, and we see no disposition on the part of local or State relief authorities to get into a preventive medicine program. So we hardly can expect to get a five dollar laboratory bill paid by them.

DR. MITCHELL. Again, of course, the conditions which exist in the different cities and counties are quite different. In many of our communities provision is made whereby the typing, for example, of pneumonia is done free. That is true in my own county whether the patient is in or not in the hospital. I know of another county where that provision doesn't exist. So that we hope in time at least that adequate financial assistance may be given through the government agencies which will permit the typing to be done without direct cost to the patient. Now that doesn't exist in your county at the present time. Do you think that there is any possibility of bringing that about?

MR. NEFF. If your committee issued a statement that that was the responsibility of governmental agencies I think it would help very materially.

THE CHAIRMAN. Would you like, Doctor, to have that go straight from the committee to the authorities in your county?

MR. NEFF. No, I think that would be a little too obvious. I think probably a statement appearing in the JOURNAL could be accepted by us and be more useful.

THE CHAIRMAN. Dr. Mitchell, will you remember that?

DR. MITCHELL. I will and will take it up with Dr. Farmer and also with Mr. Neff and see what we can do directly.

Remarks by Dr. Nelms, Chairman, Committee on Legislation. I don't believe anybody can approach medical legislation in this state without first paying tribute to Dr. Lawrence. Last year over 300 bills were introduced in the Legislature having medical aspects. These bills are not earmarked. Somebody has to go over them carefully. That lot falls to Dr. Lawrence. I don't believe there is a more faithful or a more efficient servant of the State Medical Society than Dr. Lawrence. I feel that if the members really realized the details that go to make up the legislative bureau that we would all feel like taking off our hats every time we pass it.

THE CHAIRMAN. Dr. Lawrence, stand up and take a bow.

DR. NELMS. Dr. Lawrence didn't know that I planned to pay him this tribute, but I think if you could know the inner workings of the legislative bureau that you would come to the same conclusion.

So far our committee has had no meeting.

It has made an attempt to have a meeting but something happened and a quorum was not present. However, there are certain mandates that have been given to us by the House of Delegates. I think I can with propriety discuss some of these. In the first place, when I was elected Chairman of the Legislative Committee I asked myself one question and that was this, how does legislation fit into the scheme of organized Medicine? You can't answer that question unless you ask yourself, what is organized Medicine? I feel that we owe the doctors two things fundamentally, speaking generally. I think we ought to aim to make the doctor a better doctor, secondly, that we should attempt to improve his economic status. If we do these two things, we justify our existence. We are then in a position to render the public a more efficient and a better type of medical service. I feel that the legislative committee, particularly the profession, owes not only a duty to ourselves but to the public. We don't know from day to day what type of bill is going to be dropped into the box on the Hill and legislators, committee chairman, even the Governor, will very often come to our legislative bureau for advice and guidance. So that in this problem of legislation our duty is not only to the profession but also to the public.

I think we can divide the profession into three great groups. We have first the ultra-conservative, the doctor that can see no change. Things have always been good enough for him and he hasn't yet caught the spirit of the times. Those of you who attended the last session of the House of Delegates know that we have also another group, the impatient, radical group, the group that is prone to take chances, the group that is impatient. They advocate and sponsor all types of things, things that aren't justified by reason or experience. Then we also have this great middle class that you and I belong to, a group that is cautious but not obstinate, a group that feels that we do need change, but we are not willing to plunge ourselves into a state of chaos. I feel that it is the function of the legislative committee to interpret the trend and to give sane and safe advice as to what type of legislation we should really sponsor. I want to speak for a little while about the proposed program of the legislative committee. There were certain things referred to us by the House of Delegates and most of these carry with them the provision that we must sponsor them. We have no choice. I think I am in personal agreement with most of them and we might take them up in order.

First is the licensing of foreign physicians. The House of Delegates gave us certain leeway here as to what we should do. Last year the legislative committee sponsored a bill which would make full citizenship a requirement for licensure. So far I see no reason why we should change our stand. The resolution in the House of Delegates was to the effect that we do something about this question of license.

by endorsement. I thought you might be interested in the figures compiled by the Education Department for the license of foreign physicians. During the year 1935-1936 there were 225 foreign physicians licensed in New York State. In thirty-six other states there were 114. During the last five years, 1931 to 1936, there were 843 foreign physicians licensed in New York State and in thirty-six other states there were 478. Of this number 479 were licensed by examination and 364 by endorsement. Now immediately somebody goes up in the air and says that you ought to do something about that. We propose to try to do something. There are certain fundamental questions involved. These doctors come in under the immigration quota, and it is a serious question just how far we are justified in going in determining where a man admitted under regular immigration quota can go, how far we are justified in telling him where he shall locate or what he shall do after he does locate. Now the Board of Regents have a special committee appointed to investigate this problem and it is highly probable that they themselves may come to some definite conclusion. I don't believe that the legislative committee is prepared nor should take a definite course of action until the report of the Board of Regents is available, particularly in view of the fact that there is a possibility that organized Medicine may be ultimately given a voice in their deliberations. As I said before, last year the legislative committee sponsored legislation which would make full citizenship a requirement for license, and at this time I see no reason for reversing our stand in that respect.

Now the question of nurse anesthetists. There was a resolution adopted by the House of Delegates which would limit the giving of an anesthetic to physicians and dentists except in cases of emergency. Attempt was made last year or the year before, I have forgotten which, by the legislative committee to do something about this problem. There is on file in the legislative bureau a very vigorous protest from very representative members of this society opposing this type of legislation. So that I think we can construe that the profession itself is not wholly united on this question of the nurse anesthetist. We are sure that the hospitals, the State Hospital Association, will oppose us on any type of legislation in this respect.

Some of you may have heard rumors from the State of California where their courts recently declared that a nurse giving an anesthetic under the supervision of a surgeon was not practicing medicine. This has been sustained by the highest courts in California and the hospitals are staking their all on that decision.

It seems that three years ago a physician of Los Angeles, who limits his practice to anaesthesia, on his own initiative and without consulting or advising with the county society and the State Medical Association and with an attorney of his own selection initiated an injunction proceeding against a nurse who was giving

anaesthetics at one of the leading hospitals in Los Angeles. The issue came to trial. The court ruled under the testimony given that the administration of an anaesthetic by a nurse under the direction of a surgeon did not constitute the practice of medicine and therefore it declined to issue an injunction restraining her. The poor preparation of the case, the failure of instructing the expert witnesses, the fact that the hospitals joined into the defense of the nurse, calling in members of its staff who testified that it was a common practice and that the nurse anaesthetist was under the direct supervision of the physician, occasioned the judgment that was issued by the court. Then suddenly realizing the seriousness of that court decision a cry for help was sent to the counsel of the California Medical Association. The counsel endeavored to appeal the case to the Court of Appeals and obtain a verdict to reverse. Briefs were prepared and arguments were made. They had to be based on the transcript in the Circuit Court where in that transcript reputable surgeons testified that the nurse was under their direct supervision in the administration of the anaesthetic. Based solely on that testimony the Court of Appeals declined to reverse the Circuit Court's decision. An appeal was then made to the Supreme Court for a reversal and the Supreme Court rendered a similar decision sustaining the lower court. This places on record in California courts a legal opinion that the administration of an anaesthetic by a lay person under the supervision of the operating surgeon is not a violation of the practice of medicine. The whole thing was a comedy of errors from the first institution of the action. It is thought in California that had this been handled properly and the proper witnesses been examined and if the procedure had been one of charging the nurse with a violation of the Medical Practice Act and not trying to seek an injunction, a far different decision would have been obtained. This indicates how a mess can be brought about through an individual doctor proceeding on his own initiative and without full information and knowledge of the proper method of procedure, thereby placing on record a court decision that is adverse to professional interests.

On account of the expense incurred the California State Medical Association was obligated to desist from further attempts to start a proper procedure.

The significant thing of this decision is that it is now on record in one of the courts sustained by the Supreme Court of California that a nurse giving an anaesthetic under the direction of a surgeon is not really practicing medicine. Now as I see it that does not prevent us from introducing additional legislation which will limit the giving of an anaesthetic by registered licensed physicians and dentists except in the cases of emergency. From a strategic point the question comes up—a quite important question—whether we are justified in asking that this legislation take effect immediately. It is possible that if we seek legislation this year and ask that it become effective in another year or within a few months, this would give the hospitals and physicians also, an opportunity

to prepare for this new field that is really opened to them. It seems one way out of a difficult situation.

As I said before, the committee has not yet taken a definite stand on this question. We are bound by the resolutions of the House of Delegates to sponsor some type of legislation which would limit the giving of an anesthetic to licensed physicians and dentists.

A resolution was introduced in the House of Delegates asking that the physiotherapy clause be taken out of the Medical Practice Act. The committee on resolutions asked that this be not adopted and it was not adopted. We have information, however, that the Education Department proposes to introduce legislation asking that the physiotherapy clause in the Medical Practice Act be removed. The details of that legislation or that proposed legislation have been changed a time or two and we are in full knowledge of what is contemplated at the present time. Whether any additional changes will be proposed, we don't know.

Now advertising by physicians. We are instructed to do something about that. This is an old subject and perhaps some of you have seen these various types of newspaper advertisements and circulars that some of these quacks circulate, particularly in the larger cities. The committee last year introduced a bill which would prevent any type of advertising. This bill was vigorously opposed by the daily newspapers. They took the stand that they had a code of ethics that was equally as high and as binding as that of the medical profession and they resented any intrusion by the profession into that type of supervision, and so the bill was lost. Again it is a strategic question, a question of strategy, whether we would not be justified in reintroducing this bill and leaving out the daily newspapers. It is possible that we might get the bill through if we left out the daily newspapers and we would be justified in doing this only on the ground that a half a loaf is better than none.

Now the amendment to the Workmen's Compensation Law. This was one amendment that was introduced in the House of Delegates and adopted, and that was to the effect that the compensation law be amended which would permit and recommend submission to the Legislature of New York State of an amendment to the existing law which will empower the Industrial Board to assess the cost of medical care and compensation against the non-insured employer. There should be no controversy about that. I think this recommendation really originated from our committee on workmen's compensation.

Now the lien bill. You know that the hospitals last year got their lien bill through and, unfortunately, the doctors did not get theirs. We are pledged or bound by the House of Delegates to sponsor no lien bill that does not include nurses. The probabilities are that we will endorse the same bill that was passed by the hospitals last year and add physicians and nurses to it.

On the question of medical indemnity, that is the same problem that Dr. Elliott was discuss-

ing and there is no need for further discussion there.

There has grown up in some quarters some enthusiasm for a so-called Basic Science law. Some of you have read about it. Perhaps some of you have become quite interested in it. Basic science law is on the statute books of some thirteen states. It is the law in Canada and in some of the insular possessions of the United States. The essential features of this law is that any candidate for professional licensure shall be required to take an examination in certain subjects that are called basic before he can be admitted to the regular professional examinations. Some men felt that the enactment of a Basic Science law in this state would be an efficient curb on chiropractors and other quacks. As I said before, the committee has not yet taken a definite stand on this question, because we have been unable so far to get a full meeting of the committee. However, Dr. Lawrence has made a survey of the thirteen states where this law is effective and the replies that have been received so far are very enthusiastic. It has tended to reduce the incident of the cults and from their standpoint is quite commendable. In the approach of this problem, however, there are certain things that are fundamental and in making these comments I want you to feel that it is my own reactions to this problem so far. We have in this state a Medical Practice Act whereby we say to all comers. You present two years of college work, four years of medical work in an approved college, and then you can take our professional licensing examination.

Now I personally feel that that requirement is basic. I think we ought to consider it as such. If a man meets these requirements, then wants to practice osteopathy, or if he wants to practice homeopathy, we might stretch our imagination and our liberality and say. If you want to practice chiropractic, all right, but meet the same educational requirements that we do.

Now I also feel that one of our greatest weapons against official recognition of chiropractors in this state so far has been this one argument. If you require two years of college work, require four years of work in an approved medical school, with the doctors, why require any less preparation for any other type of applicant for the healing art? Judged in this light, the Basic Science law does not apply to this state as it does to many other states, California for instance. They have four licensing boards. They have a licensing board for the regular practitioners. They have another for the midwives, another for the druggless healers, and so on. So far in this state we have succeeded in keeping from the chiropractor his most prized possession, and that is, official legal recognition. There is no such thing in New York State as chiropractic as far as the law is concerned, and I personally feel that we should stick to the minimum requirements that are now set forth in the Medical Practice Act and not create by implication an intermediate field where we tactfully admit that there is a sphere somewhere for healers that are less-fitted than we ourselves.

This in substance will be perhaps the major part of the legislative program for the coming year. We never know what is going to be dropped into the box by individual legislators. Many times the bills are of a type that we can sponsor, that we can go along with. Many times they are bills that we have to oppose. I hope we can keep this fundamental thing in mind, however. I think we should concentrate on the things we need the most and not clog our program with a lot of hodge-podge attempts to revolutionize medicine.

This brings up the last point I want to make, and that is our legislative organization. I was amazed at the efficiency with which this organization functions. The office of the legislative bureau, headed by Dr Lawrence, gets these bills very shortly after they are introduced. Dr Lawrence goes over them. Bulletins are sent to the chairmen of the legislative committees and within a very short time each chairman of each county legislative committee is aware of what has been introduced within a few hours before. Now it is very obvious that the state committee and Dr Lawrence in particular cannot concentrate on every legislator. We feel that our job should be to contact and influence the leaders, but the individual legislator is the problem of the local county society and we feel that it is the job of the legislative committee to contact the legislator in his district, find out where he stands on certain proposals, find out what his attitude is, make known the wants of that community to that legislator. We will try to give you the cue as quickly as we can as to what is a sound and substantial attitude on these problems. Thank you.

THE CHAIRMAN I think the last item that Dr Nelms brought forth might be discussed first. Then we might possibly retreat to the individual debatable laws just for our interest. This matter of help from the legislative committee to the counties and help from the counties to the legislative committee seems to me to require quite a little concrete phraseology. For instance, I heard last night from one of our members the idea that we should be careful with candidates for office. We shouldn't apply too much apparent pressure at that time but should contact legislators locally after election through the county societies, and have that an outstanding piece of work that the county does. Dr Podvin has some ideas on that subject.

DR. PODVIN I don't know that I have anything to add to the very excellent report that Dr Nelms has given us, but my idea, expressed last night at the meeting was that some times we local men, county society groups, take ourselves too seriously. We think that it is our duty to regulate all the legislation that is presented and determine what should be passed and what should not be passed whereas I feel that if we left most of that to the state committee who are in a better position to judge it, than we are, except certain measures that may affect us locally, and concentrate more particularly on the individual legislators in our dis-

trict, I think that is the essential work which the local legislative committee can and should perform. Dr Lawrence, of course, cannot do that, but those of us who live in the counties know who the legislators are. I know two or three years ago in my society we had a very pretentious program. We started out with questionnaires and so on and so forth, but we didn't get very far. In fact, I think we did more to impede than to assist in legislative matters by that particular program. We have since discontinued it and concentrated on the individual work with the legislators.

DR. LAWRENCE You are not legislative chairmen, you are the secretaries of the county societies. You can, however, assume the responsibility of making certain that you have a legislative chairman in your county and that he has a committee, the personnel of which we should know. You know we send the bulletins to the members, not only to the chairman but to the members of the committee, each member. In some instances the chairman of the county committee prefers not to have the members of his committee receive the bulletins. That is only true in two or three instances, but we would like to know the names and addresses of the members of the legislative committee so that we can send our bulletin immediately when we begin to send them out, which is about the first or second week in January. We will keep you informed, I mean, we will keep your committees informed. We can add to that bulletin, too, for that matter, other members of your county society if you think that your chairman would like to have them receive the bulletins. We also send the bills to the chairman. We don't usually send those to the members of the committee, because they are a little difficult to get, and after all we send them to the chairman with the analysis that we prepare, and we expect and receive comments from the chairman. You know that your chairman is one of an advisory committee of sixty members that Dr Nelms' committee depends a great deal upon. You heard him say that with regard to this bill on anesthesia administration. He referred to our files to see what comments we had received on that bill two years ago. Our files are very complete. We have comments there on bills that were introduced ten and fifteen years ago and it keeps us informed. At the same time that information is for your benefit too and for your county chairman. Your county chairman, if he will assume that responsibility, realizing that he is a member of an advisory committee and that we greatly desire—I do, and so does the committee—his assistance and cooperation, you will help the committee very materially.

THE CHAIRMAN Dr Lawrence, would your mind saying a word more on the request that occasionally comes out from you or from your committee for letters to be addressed to a legislator on any particular bill from his home town, home place, and the purpose of those letters?

DR. LAWRENCE Yes, supplementing what Dr Podvin said a minute ago, the most effective

work, after all that is done with any legislator, is that which is done in his immediate community by the people who are voting to support him. Letters sent promiscuously to legislators who are not in your district don't as a rule mean anything. They are passed into the waste-paper basket. The man in the Legislature has gotten there by votes and the people who vote for him are his bread and butter. He has to please them or at least he has to understand how they stand and be in touch with them. So you have your strongest appeal immediately to your man that represents you. But there are times when a man is sympathetic to our work and he may come from a small district but he may be a very powerful man, a man of influence in the Legislature, and he would like to work for us but probably the people on the other side have been more active and he has received many more letters probably or requests or communications or he has requests and communications from very important influential people and he looked at those and then he looks for our support. Many times they will say to me now you think this is all right. You think it is a good measure, but you haven't taken the pains to help me support you. Here I have on my desk, and you can see them, you may read them if you want, these requests for opposition to that measure, or vice versa, and none for it, and he says they are wise to this too, and they come to me and they say, well, you can't very well take a position against us.

THE CHAIRMAN Yes, and these letters should go to the particular man from the particular district and from nowhere else.

DR. LAWRENCE Yes.

THE CHAIRMAN So that he can show them to his opposing people.

DR. FREY, *Queens County* I should like to ask when a bill is introduced which has some medical implication how the attitude of organized medicine in regard to that bill is determined, as to whether we shall endorse or oppose it. I ask that because last winter was a little disconcerting when the members of a New York society went on record as being vigorously opposed to State organized medicine. Do you want to answer that?

DR. NELMS I am not familiar with that attitude. This is my first year as chairman of the committee and I think Dr. Lawrence is in a better position to answer it than I am. I don't mean to pass the buck. I might say this, that in general the committees this year will endeavor to determine the attitude of organized medicine and the particular groups in question. There may be times, however, when certain things have to be left to our judgment. We never know from day to day what is going to be dropped in the box. In the last days of the last session things were quite hectic. The sessions were long. I think one or two lasted all night. I know I left the halls at twelve o'clock and the next morning at seven Dr. Lawrence called me up and said that he had stayed all night, some times it is—well you just can't determine your position

beforehand on a lot of things that somebody else drops in the box. I prefer to hear from Dr. Lawrence.

DR. LAWRENCE The technic is very simple. You have already alluded to it a number of times. The bills are introduced and dropped in the box, as the expression is, and the next morning I have a copy of them. Immediately a copy of that is sent to each member of the legislative committee. If I don't get enough copies on the Hill I have them typed or mimeographed and sent out. So that the committee gets that bill within twenty-four to thirty-six hours from the time it is introduced. Of course action on a bill isn't immediate except in the last couple of days. Then it may happen inside of three or four days. That mention of that bill and its title is reported in the next bulletin and you know we send bulletins the early part of the season weekly. A little later, we send them at two or three days intervals and toward the last they are sent daily, so that the chairmen are informed. Then as soon as that bill is printed, which is the early part of the season, in about a week's time toward the end of the season it is within twenty-four to forty-eight hours. That bill, the printed bill, is sent to the legislative chairman. In the meanwhile I ascertain the origin of the bill, what is back of it, who are back of it, as near as I can on the Hill, and any other additional information, and I give that to the legislative committee. They read the bill and use their judgment. They decide from reading it whether they think it is a good bill or bad and inform me to that effect. In the meanwhile, I get back comments from the county chairmen as to whether they think it is good or bad. The forepart of the season action on any bills introduced early in the session is rarely taken up before Washington's Birthday. We have all that while in which to study these bills. Of course, towards the close of the season action, as Dr. Nelms has indicated, is much more hectic and much more precipitate, but we have this advisory committee of sixty members who report upon the bill and then the regular committee. The regular committee has in addition to that, another advisory committee of ten that they appoint and from these various people the information is received and has the majority of them, I mean. A majority action from them, reports from them indicate the action. Of course there are one or two instances too, where bills have been presented to the executive committee, and the executive committee has taken action and directed the legislative committees how to act upon the bill.

THE CHAIRMAN Ordinarily speaking, you do not have any great doubt, do you?

DR. LAWRENCE No, ordinarily there is no question about the bills, and may I say in that connection too, that a bill such as that optician bill last year and the optometric bill, many of those, when they are sprung on a man, look as though they were much different from what they are. The optometrist bill last year was practically the law. It was just a revision of what is in the law at the present time, except that

they increased their educational requirements. It was really a good measure except they put in one clause which read as though it were going to prevent a physician from fitting his own glasses. That was bad. Then the opticians have no recognition in the law at the present time and they wanted a measure that would give them an opportunity to limit the practice of fitting and filling glasses to persons who were qualified to do it. At the present time any jeweler or anybody can hang out a sign and fit glasses. Now that was an honest effort to bring again an ancillary practice of medicine or an ancillary feature of it under regulation and control, but it wasn't generally understood. The doctors were divided on it, very much divided on it. In certain sections of the state they were wild against the optician bill, and others were very much for it. It became at one time our hottest spot, but it cleared itself up, and I think next year the thing will work out all right. Does that answer your question?

DR. FREY: Thank you, Doctor.

DR. GAUS, *Essex County*: I just want to substantiate what Dr. Lawrence has said in regard to telegrams and the effect on Assemblymen and Senators.

Remarks by Dr. Hambrook, Chairman, Committee on Public Relations: The Public Relations Committee has been in existence over ten years, and during that time certain information has been obtained from conferences and from meetings with other organizations, both official and lay, which have given us a set of precedents which we think are wise in guiding not only our own activities, but the county medical societies. The aim of all these, of course, is to provide the public and each county society with the best possible medical care. The achievement, however, of these facts will depend upon many things. Among those we might mention three as all-important.

First, to create harmony among all medical and public health workers. This I feel is very important. Many times we, as medical men, are inclined to be antagonistic against any organization that takes up anything that savors of preventive medicine. We forget that these people may be animated and undoubtedly are animated by very fine ideals, and instead of criticizing and opposing them, our best procedure should always be to cooperate with them. Let us take the jump in as many cases as we can and institute these things. But if others do institute them and start them, then it would be to our best advantage to cooperate with them, to guide them, and give them the benefit of our knowledge.

Secondly, an important thing to aid the public to recognize what is good practice and good medical service. I don't believe that ever in the history of medicine in this state has it been more important to establish this principle than at the present time. One of our officers has stated that the public can be trusted when properly informed. I believe that it is true in most instances and where so many conflicting ideas are prevalent today regarding State medicine and panel practice, et cetera, the public can be left

to judge as to what is best for them, but we in return must show them exactly what we are doing for them in the way of good medical practice. I believe that in the state of New York this is possibly as widely diverse as in any other state in the union. We should therefore in every way possible inform our medical men by postgraduate work and others of the modern trends of medicine so that the public themselves will realize our importance in the community, by doing that there will be a great deal less danger for them to want to adopt any other form of practice than what we have at the present time.

Thirdly, by stimulating physicians to become active members of public movements, especially movements pertaining to public health or medicine, both curative and preventive. I think that there is a big field in this particular principle, and many avenues are available to us. The civic groups in our respective localities, especially the clubs doing service work all have some form of medical activity as one of their main objectives. I think that we should endeavor to promote our own activities in these organizations. Certainly members of the organizations should be on the health committees and they should be activating forces which will develop the policies which these different lay organizations are undertaking.

The technic, naturally, of putting these principles into operation will depend a good deal upon the county medical society itself. You cannot promulgate a program which will be state-wide and which can work in each county. It must have its local aspects. As Dr. Elliott said in speaking of the insurance work which was done so well in one part because they all knew each other, I think that certainly stands true for activities in our county medical societies. It seems that our local organization and our patients and our friends have a better knowledge of each other than certainly any other portion of the state can have of us. So that therefore the basic need, I should say, is harmony and cooperation between the physicians, represented by county medical societies, and official and unofficial health organizations. Physicians should take a civic interest in public health and medical problems. Wherever public health can be directed by the local physicians, it should be directed, and where it has been started by other activities, lend our cooperation as far as possible.

During the activity of this state committee several years ago, in order to determine what activities were going on in each county society the county groups were asked to take a survey and it was surprising to the members of the state body to find out the amount of work that was accomplished and was being done by the different county societies. In fact, it was informative to the county medical societies' members themselves, and we are this year going to follow-up (so that they will not get rusty) by asking a few simple questions in a letter which will be forwarded to the chairman of the Public Relations Committee. The questions will be about as follows:

1 What has your committee done to help establish a working relationship with the governmental and lay health organizations?

2 Are you cooperating at the present time in any important piece of health work?

3 What educational health activities are occurring in your county?

4 Is the profession assuming a leadership in your county in all health measures?

We have certain definite dictates from the last meeting of the House of Delegates which I will just briefly recite. It has been recommended by the House of Delegates the formation of county health relations councils in each of the counties of the state. The first meeting after the summer recess of the Public Relations Committee will take place tomorrow in New York City and many of the matters which I will refer to today have not been definitely decided or policies adopted.

Secondly, and this is very important and can be brought up here today, it was recommended by the House that a joint meeting of the legal and medical professions by county associations be held once a year. This was thought very advisable for one reason, the increasing number of malpractice actions in the State of New York. We feel from conference and from talks with many of our lawyers that if there were a better understanding between the legal and medical professions many of the contemplated actions would have been stopped in their incipency. By assembling at a meeting in a social way and by letting the lawyers of our respective counties know exactly what we are trying to do and accomplish I think we must establish a relationship which will work to our decided advantage in the future, and this will be communicated in a letter to each of the county groups.

Examination of school children. This was also referred by the House of Delegates. About four years ago the Public Relations Committee in conference with the Education Department and the Health department established this fact, that the Education department was very anxious that the medical doctors make the examination of the school children, provided they make it thoroughly and upon blanks which allow rapid dissemination of the knowledge in the office affected. The trouble has been that many of the doctors have not taken up this matter for various reasons, many of them, apparently without any justification. The examination of the children must be thorough and be honestly done, and that was one of the objections that we had in the beginning, because it was proven that in some instances the doctors had examined a child in their office, one of their patient's children, and without any thorough examination at all had answered the questions satisfactorily, giving a clear bill to the child. That, of course, is not right or fair. But the fact remains that the Education Department of the State of New York would be very anxious to have more and more examinations of the school children performed by the family doctors, provided that they

are done properly and on forms which are supplied by the Education Department.

The sub-committee on the Deaf and Hard of Hearing. Last year two measures were passed by the legislature and signed by the Governor. One of these is of importance to us as medical men, because we are directed to notify the Health department or the Education department of any child who is deaf or hard of hearing so that proper means may be instituted early to correct, if possible, the hard of hearing from becoming worse and to get the deaf child under proper educational facilities. The exact procedure that would be carried out in this has not yet been determined. In the same way from the last House of Delegates reported was the care of children with defective eyesight. Many of you members who attended the House of Delegates meeting will remember that it was recommended by the Public Relations Committee that children who had vision defects greater than 20/30 should be examined by a doctor and quite a discussion took place in the House of Delegates. It seemed as though the matter was not thoroughly understood and it was referred back to this committee. A sub-committee will be named to handle this matter and as soon as the proper procedure is determined you will be notified.

Mention was made before of the JOURNAL as a means of keeping the members informed of the activities of this committee. It has been determined by the Publications Committee that a certain number of pages of the JOURNAL will be devoted to committee activities, and in this way as soon as the committees are in active work their activities will be published in the JOURNAL so that you may read and determine for yourself exactly what has taken place. The committee has not determined yet as to whether they will hold regional conferences as in previous years. I would like an expression of opinion here today as to that. We have tried it first in a small way at our district branch meetings. It didn't seem to work very well, because I believe it detracted from the district branch activity and program itself. Then we next, or the chairman of the committee then divided the state into sections and had sectional meetings at which the members of the Public Relations Committee attended and listened to the problems and tried to give advice. This was not done last year and whether it will be this year will depend entirely on how you may feel about it. I sincerely hope that any county society that wants information on public relations matters at any time will communicate with the chairman or, as was said here today, with the member of the committee nearest to him. In that respect this year I have asked one member of the Public Relations Committee to attend the district branch meeting, the one that will be adjacent to his home, and I am sure that we are always at your call. We will always be glad to cooperate with you in every way possible so that relations will be put on the finest basis in your county. Thank you.

Remarks by Doctor Kaliski, Chairman, Committee on Workmen's Compensation. I am very

glad to have this opportunity of appearing before the Secretaries of the County Societies to talk on the subject of the Workmen's Compensation Amended Act. The amendment really has already produced a great alteration in medical practice in certain parts of the state. I think we can say that in the Metropolitan District, particularly in the five counties, that the act has resulted in distributing medical work among practitioners generally and has undoubtedly increased the quality of medical care rendered to injured workmen. Now since the amendment of the law was brought about largely to effect an improvement in medical care and to provide for the workmen, the injured workmen, not only better medical care but also honest testimony at the hearings of the Department of Labor, I think that the drawing into this work through the amendment of a large number of competent practitioners in the community has had a beneficial effect all around. I think we can say from conditions in the Greater City, for example, that those men who in the past largely controlled this work are not getting as much work as they were getting last year. That effect is already known. Now the committee has been set up and a bureau has been set up to be of service to the various county societies and to the county societies' boards. We want to cooperate. We want to try as far as possible to take off your shoulders those problems which can be solved by the State Committee on Workmen's Compensation and to leave to you those problems and those duties which you must necessarily perform in your local counties. We stand ready to do that and although we have received a large volume of inquiry from various parts of the state, we feel that we probably could be of service to some of the other counties who have not as yet been in touch with us in regard to their problems.

In the limited time at my disposal I shall merely touch on some of the important matters that are facing the committee and the county societies at the present time. One of the first things that I wish to speak about is the fee schedule. The State Committee on Workmen's Compensation has made a determined effort with the Commissioner and with the Industrial Council to have them promulgate for the remainder of the state an unchanged metropolitan fee schedule. We have been successful so far in preventing the Commissioner—or in inducing the Commissioner—that is a better word—in not making the reduction that we feel he intends to do, perhaps in the near future. As you know, the Commissioner, as a result of his conferences with his own council and with various employers' organizations, and carriers, feels that a discount of ten per cent should be allowed those who pay the bills, to communities of 75,000, and a discount of fifteen per cent from the bills of doctors in communities of 35,000 and less, that in all communities of 75,000 and over the metropolitan fee schedule should prevail.

I won't take up your time to tell you how many conferences we have had on this subject. As you know, we did have a conference in

Albany. It was called by the Commissioner. At that conference the county societies turned out in good force and made a good impression upon him in regard to the prevailing rate throughout the state, but in spite of that and based upon, I believe, a fallacious economic argument, the Commissioner feels that, in view of the fact that wages are lower in some of the communities throughout the state, particularly in those of 75,000 and less, that therefore the bills for compensation work should also be lower. As I say, we have at the present time prevented the Commissioner from taking a definite stand in promulgating this schedule, much as we should desire to see the schedule promulgated.

At the last meeting of the Executive Committee of the State Society we recommended that. The five medical members appointed at the suggestion of the President of the State Society he appointed on this Industrial Council of fifteen members the advisory council to the Commissioner of Labor, should take a more determined stand in insisting upon the Commissioner promulgating the metropolitan schedule for the entire state. It is our opinion, based upon some experience, that the promulgation of this fee schedule, this metropolitan fee schedule, for the remainder of the state outside the metropolitan area will not materially increase the cost of medical care.

Now another very important matter that confronts us is the question of the licensing of Roentgenological laboratories. You know the law provides for the licensing of separate laboratories. It also says that these laboratories must be supervised and operated by qualified physicians. It places the licensing of these laboratories squarely on the shoulders of the local county society or its compensation board.

We heard something about dropping bills into the box at the last moment. The Workmen's Compensation amendment called for the only supervising and operation of these laboratories by qualified physicians. Through certain interests at the very last moment on the very last day before the amended act was brought up for a vote, these interests succeeded in scratching out the words "owned" and left in the two words "operated and supervised." At the present time the law reads that such a laboratory shall be operated and supervised by a qualified physician. It leaves the question of ownership open, and in accordance with the ruling by the Attorney-General on this subject the Commissioner has the right to license separate x-ray laboratories owned by laymen or corporations. We have protested. We have submitted a legal brief. At the present time we are faced with the situation where it will probably be necessary for the state society to take legal action to prevent the licensing of these lay-owned or corporate-owned x-ray laboratories.

There are two questions involved there. First, these two questions confront your local county societies. Shall the local county society, for example, license a doctor who it knows is in charge of a lay-owned laboratory? Such a case is now pending before one of the county boards.

SECRETARIES' CONFERENCE

1449

The county board has not been able to make a decision on the point, because this particular doctor has not made a proper application. When he does, this local county society will refuse to license this doctor, will refuse to qualify him, rather, on the grounds that to do so would be to put him in charge of a laboratory owned by a lay person or a corporation, and this in the opinion of the state society is a violation of the Medical Practice Act. Now whether the amended Workmen's Compensation Law with its provisions to license such laboratories supercedes the educational law of this state is a question that only the courts can decide, and I am glad to say that with the consent of the Executive Committee we are going to bat on this action and will probably either defend an event that the Commissioner licenses such a lay-owned organization. My advice to the local county societies in the event that they receive a request for the granting of a license either to a physician connected with such a lay-owned organization or a request for licensing of a laboratory, that such request be sent to the state society before action be taken by the local county society.

As you know, we contemplate and are now proceeding to insert in the state directory the qualifications of all physicians under the Workmen's Compensation Act. This will be of great help to employers of labor, to the insurance companies, and to various state organizations in enabling them to determine whether a doctor has been qualified under the law, and, if qualified, what his qualifications are.

The Journal Committee has ruled that in order to make the procedure feasible the county societies cut down the designations that they gave to physicians. We are not criticizing the county societies, because this work had to be done in great haste without much experience at the beginning, but we have asked them to cut down these designations to a maximum of six letters.

The vast majority of the county societies have already done this and have simplified their classifications. A number of the county societies have not yet sent in their completely revised lists or, if they have sent in lists, they haven't given us the names of the physicians who can qualify or who have been qualified in the last two or three months. I believe the Directory is going to press within the next few weeks and I urge the secretaries of the county societies or the chairmen of the boards, Workmen's Compensation Boards of the county societies, to let us have the lists at the earliest possible moment. This is a new departure. It is a new field and we hope that there will be as few mistakes as possible. But if there are mistakes I am sure you will all bear with us because the work of compiling this directory has been a very great burden on the Journal Committee.

I am happy to be able to report that we are now ready with the plans and procedures for arbitration. We have met over a period of a number of months with the insurance carriers and representatives of the Department of Labor,

particularly of the Industrial Council, and have set up an arbitration procedure that we believe will enforce the payment of a doctor's bill. As you know if you read the law carefully you will find that there is no way, once the doctor has had his bill O.K.'d by a carrier or employer, of enforcing the payment of the bill. A case that goes to arbitration carries with it a means of enforcing the payment of the bill. In other words, by setting-up the arbitration proceedings in a legal fashion we have done this with the help of the American Arbitration Association, the award of the arbitrators becomes a legal paper that can be entered in the court as a judgment and can be enforced against the employer or carrier.

The question has arisen whether arbitration proceedings can be started in counties outside the metropolitan district in view of the fact that there is as yet no official fee schedule for those counties. I believe that arbitration may begin, and that the cases may be arbitrated on the basis of the prevailing rate until such time as the metropolitan schedule or other schedule is brought into being for the remainder of the state. I believe that this will immediately clear the calendar of a large number of cases that are pending throughout the state in regard to the fairness of the bill and, secondly, for actions on lifting. We arbitrate the two things. We arbitrate on the question of the fairness of the amount of the doctor's bill. We also have a right to arbitrate if a doctor believes that a case has been improperly lifted from him either by an employer, an insurance carrier or anyone else. We will provide the forms necessary before the setting up of arbitration and for the submission of these cases to arbitration where the doctor believes his case has been improperly lifted from him. There is a very ticklish situation that we have had to deal with from the very inception of the passage of the law, namely, a discussion of this problem in detail at the time. We have had numerous conferences with the hospitals on the question of the relation of the hospital to the doctor in regard to Workmen's Compensation but this is only one phase of a very complicated problem, the relationship of the doctor to the hospital in many aspects. We feel that the setting up of a special committee by the President of the Society will enable us, among other things, to bring about such relationships with the hospitals that we may be able to solve, among the other problems that confront us, the problems of the relation of the doctor and the hospital in regard to Workmen's Compensation.

A question has arisen as to whether the state society should undertake to print the forms, the doctor must submit when he accepts a case under the act. This is the function of the Department of Labor without a question. The Department of Labor should provide physicians with the necessary forms to make the necessary reports. We understand that the Department of Labor is reluctant to provide these forms in quantities necessary not only to the doctor who uses an occasional form but to those physicians

who do a large amount of industrial work, and the question now arises as to whether the state society should print these forms and sell them to the doctors at cost or slightly above cost or whether we should insist upon the Department of Labor printing the forms as provided in the law. It is a question of policy here, whether we should stand upon our rights in a matter of this sort, which is perhaps a minor matter, in order to gain good will as the result of a gesture, let us say.

Now there are many other questions that no doubt occur to you that I should speak about, but I believe the time allotted to me is drawing to a close and I would rather answer questions than make a speech. I feel that in spite of the amount of work that has developed upon the committee in the past year and a half that under the circumstances we have done as good a job as possible with the cooperation that we have received from the county societies throughout the state. There has been a surprising lack of friction. There has been uniformity of action and of thought along practically all lines with the possible exception of the fee schedule, and even there I believe that we have done as much as could possibly have been done under the difficult situations that arose and had to be met as emergency situations.

DR. DI NATALE Our county society has asked me to take up this point. One of our doctors is charging a company with lifting a case. I have written to Doctor Kaliski about this, and I wish he would briefly describe the procedure that we are to follow and also whether or not that company or the employer is allowed an attorney and whether he can cross-examine the doctor and the board, and who pays the expenses of the hearing.

DR. KALISKI Under the law a case of lifting must go before an arbitration committee. The doctor will make an application to have his case heard by his county society on a form that will be provided.

DR. DI NATALE Who provides the form?

DR. KALISKI We will provide the forms. Thereupon the company will be notified of the demand for arbitration of this case and the grounds will be given. Then an arbitration committee will be set up consisting, and this is according to law, of two physicians qualified under the Workmen's Compensation Act, designated by the President of the County Society, two physicians designated by the carrier, and these four physicians will meet as an arbitration board, will give the doctor an opportunity to be heard, to present any witnesses that he may wish to present. The carrier or employer will be granted the same privilege.

The question of counsel has been discussed. We haven't stressed it, but where counsel is required, is demanded, counsel may be permitted to appear. The proceedings will not be according to legal formula necessarily. The ordinary rules of evidence need not apply. In other words, the four arbitrators may carry out any procedure that they see fit in order to determine and render justice in the particular action. The four arbitrators will hear all the evidence, will retire, and decide the case. If they cannot agree, then

they must call on a fifth man. They must decide upon a fifth man, also a member of the state society. He may, if he so desires, reopen the case and hear additional evidence, or he may decide on the evidence submitted at the hearing, and his judgment is final. That is the procedure.

The arbitrators are paid a fee of \$10 each, this to come out of a fund collected from a discount or a charge of five per cent on the award rendered in every bill arbitrated. Does that answer the question?

DR. DI NATALE Yes and no. Mr. Hugh Murphy in receiving the same request stated that this case of lifting goes to the Compensation Board first to decide whether or not lifting has taken place.

DR. KALISKI I am sorry to disagree with Mr. Murphy but I can assure you that he is wrong. The Compensation Board of the County Society?

DR. DI NATALE Of the county society.

DR. KALISKI I must also disagree. The doctor has a right to begin an action for lifting and it is decided by arbitration and not by the county board. The county board may suggest to the doctor, after an investigation, that he probably has no grounds on which to begin a lifting action, but the doctor, a qualified doctor, has a right to a procedure by arbitration. That is the law.

DR. DI NATALE Well, there is no bill to be arbitrated.

DR. KALISKI The penalty for lifting is either the full amount that the doctor who succeeded the doctor who claims lifting got or any such part of that amount as the arbitrators may think sufficient.

DR. DI NATALE This doctor first wants to get the board to state that the case was lifted and then wants the bill arbitrated after that.

DR. KALISKI I have given you the procedure. Doctor, it is undoubtedly true that the board has a right to make an investigation for itself and find out the facts in the case as far as possible.

DR. DI NATALE Whether the case was lifted or not?

DR. KALISKI Whether the case was actually lifted or not, but that isn't binding on the doctor. The doctor has the right under the law to begin a lifting action and that action must be carried out in the way I have described. You can probably dissuade him if you think he has no grounds but that is his right under the law.

DR. DI NATALE We don't want to dissuade him at all.

DR. MASLON, Warren County Complying with Dr. Kaliski's and your request to send in the list of abbreviated symbols of the Workmen's Compensation Act to your department, is it necessary for us to send that same abbreviated list to the State Department?

DR. KALISKI I am glad the Doctor brought that up because if the county society will so notify us we will be very glad to submit the list to the Commission. Some county societies have sent the list to the Commissioner and a duplicate to us. Where the county society

simply sends in one list, if they will so notify us, we will send a duplicate list to the Commission.

This gives me an opportunity to read off the list of counties from whom we have not yet heard in regard to the simplification of the symbols. Perhaps some of these counties have in the last few days sent in their simplified list. These counties, Cattaraugus, Clinton, Genesee, Cayuga, a few in Chautauqua, Chemung, Franklin and Livingston, Niagara and Ontario, Orleans and Otsego, Albany, Broome, Rockland County, Saratoga, a few in St. Lawrence, and a list that hasn't been revised so far as we know from Sullivan and Wyoming. The idea of course was to correct the codification begun by the county societies under the belief that a physician should be granted every symbol, every letter, in which he said he had any qualification, but it has been found that it is not necessary to give the average physician more than X or if he has some more experience in minor surgery, XM-5. That is the average practicing physician. Where a physician possesses more than the average ability in a given specialty, for example, if a man who is doing general practice is also doing some eye work or some skin work, or perhaps has a position in a clinic or in a hospital but is not specializing in that subject, such an individual may be qualified in addition to the X in that particular symbol. Some of the county societies in the beginning gave physicians as many as six or eight or even more symbols and it has been found unnecessary and impractical to include such a long list in the Directory, and I hope that these records will be corrected as soon as possible, because as I said before, the Directory is going to press very shortly.

DR. WHITE, *Cortland County*. I want to ask this for the benefit of a dentist in our hospital. He doesn't seem to be able to be classified under oral surgery and I would like to ask whether or not that can be done or just who an oral surgeon would be.

DR. KALISKI. Under the amended act dentists are not included. In other words, a patient has not the right of free choice insofar as a dentist is concerned. The only oral surgeons who have been included in our list are those in possession of a medical degree. Dentists may now accept compensation cases if they are referred to him or if they go to him. He must, however, get authorization in order to be paid for his services.

DR. GAUS, *Essex County*. The question arose in regard to the insurance company sending out letters in which the law was quoted. Following their statement they inserted a paragraph which said "Of course, we are very anxious to furnish the very best medical attention to our clients and therefore, if they have no choice, you should send the patient to Doctor so and so or Doctor so and so." That has arisen in our county and a couple of the doctors are on the warpath. They reproached the committee and said that we were responsible for it, and they have been circulating it around. I asked them to write a complaint and they said they would settle it in their own fashion. I want to know what the law is.

DR. KALISKI. The question has arisen as to the right of an insurance carrier to send out a list of qualified physicians to employers. The Industrial Council has ruled against the posting of any notice containing the names of physicians in any industrial establishment or office covered by the Workmen's Compensation Act. The Medical Society has taken the position that the carriers should not send to their insured the names of qualified physicians whom the insured or the employer might call upon in case of the waiver of right by the patient of free choice. Some of the insurance companies have contested this ruling and I believe that the Industrial Council will either next week or the week thereafter or the week after that take up this question again. We feel that it is contrary to the spirit of the law for the insurance carrier to notify an employer of designated physicians who are competent to do work under the amended act. We have taken the position that if the employer so desire the State Society and the county societies will combine and issue to employers of labor in this state a list of physicians arranged in accordance with definite localities. Of course, this will be a very big job in the big cities, but we are ready to do that. By the preparation of this list for the Directory already now in possession of the districted list of physicians, the society has taken the position that it should be given the opportunity to give any employer who desires a list, a list of physicians in the locality or in the community if the community is a small one, thereby not playing any favorites.

THE CHAIRMAN. In other words, a complete list?

DR. KALISKI. A complete list. The company, as I said, is contesting this viewpoint, claiming that under the law the employer has an obligation to provide medical care where the employee waives his right to free choice. Now there is another way to handle the situation and that is the way I believe that the local county societies may handle the situation in case the ruling is adverse, and it has been successful in some counties. The sending out of a list of physicians by an insurance carrier not to be posted but to be kept by a foreman or by a member of the firm is, I believe, a violation of the solicitation act. A physician whose name is on such a list may be notified and advised to have his name withdrawn from such lists. We have done that in New York County and it has been quite successful. The doctors in some instances did not know that their names were on these lists sent out by certain carriers. They advised the carriers to remove their names because they were in fear of the penalty provided in the law for solicitation.

DR. LEWIS, *Livingston County*. I have been asked to raise this question. What should be the procedure when a physician finds that a certain industrial plant persists in specifying to their employees one or more physicians in the community?

DR. KALISKI. Before or at the time?

DR. LEWIS. At the time of the accident.

DR. KALISKI The insurance carriers through their attorneys have taken the stand that it is the obligation of an employer to see that the injured employee gets proper medical care and they claim that when an employee is injured they have a right to point out to him, as the law does in that placard that is issued to every insured person, that the patient first has the right of free choice. He may select his own doctor, but if he refuses or doesn't desire to select his own doctor that under the law it is the employer's obligation to do so and therefore they say that the employer has the right to recommend. Now there is a very close line between recommendation and intimidation. In New York County, in the New York area at any rate, a number of insurance carriers have been hailed before the Industrial Council and asked to explain their action in regard to this procedure. I believe that we would have to handle each case on the merits. If a large industrial organization is attempting to intimidate its employees into calling on their selected doctors, I believe that the local county society should make an effort to cite such an organization and the Industrial Commissioner will call a hearing and the matter will be looked into.

DR. LEWIS In our particular instance the patient was directed to go to the office of another doctor, not an emergency that called for immediate attention, but a minor injury, and he was directed to go to the office of either Dr. A or Dr. B.

DR. KALISKI What was his desire?

DR. LEWIS He wasn't asked. He went to his own physician who was not one of those specified and signed the statement that he had been instructed to go to one or the other of these physicians.

THE CHAIRMAN By implication his desire was to go to his own doctor.

DR. KALISKI Of course, we have to depend upon the individual too to help enforce the law. The employer probably was trying to intimidate that patient, but the patient exercised his own right of free choice. In the event that such employee is discharged, as often happens, from his employment because of the fact that he did not visit the doctor selected by the employer, I feel that such a case should be brought to the attention of the Department of Labor. There is a penalty under the Labor Law for intimidation under the general Labor Law, not in the amendment.

THE CHAIRMAN Do you not think, Dr. Kaliski, that this particular instance should be brought up?

DR. KALISKI Yes, I think this particular instance should be, but I think that often the statement of an employee has to be investigated before action is taken. Many such cases have been investigated, but very few have stood the test of investigation.

THE CHAIRMAN And the investigating is the part of the Compensation Board?

DR. KALISKI The local county board.

DR. LESTER I wish to ask Dr. Kaliski if

there is any geographical limit on the desire of a patient to have his own doctor, like county limit or village or city or town limits. A case like this came up. A man in a neighboring city to Seneca Falls, where I live, sixteen miles away, was employed in a large firm and received a hernia. He desired to have a doctor in Seneca Falls do the operation and specified that, which was finally done, very much against the will of the company, but it was granted, because he made the specified reason. Now that is another county, that is, crossing a county line. Is there any geographical limit?

DR. KALISKI There is no geographical limit. A patient has the right to select his own physician and within reasonable limits to change his physician, and the law says for any cause under rules and regulations prescribed by the Commissioner. In a question like that, there isn't much at stake, but it might very well result in complications. For example, a patient in a small community might have a minor injury and might feel that he wanted to go to a doctor thirty or forty or fifty miles away, might want to be reimbursed for travelling to that place or, on the other hand, he might call a physician from a distance and expect, and the physician might expect to be reimbursed for travelling an unusual distance to the patient. Now that would become a matter for arbitration undoubtedly, because the companies would object to paying a doctor from New York City, let us say, to go up to Poughkeepsie to see a patient. I believe that under the Labor Law and under the rules and regulations prescribed by the Commissioner that sort of thing would not be tolerated. A physician would have difficulty in collecting bills under those circumstances, except in emergency, of course. I feel that while a patient may go from one county to another he would not be permitted to go from one county to another or to call a physician from an adjoining county, which would result in increasing the cost of medical care inordinately, and that is an exceedingly important point. We stand to lose as much by the inordinate increase in the cost of medical care as the carriers do if it is found that as a result of a year or two of the operation of this new amendment the cost of medical care goes up to an extraordinary extent and I am quite sure that if that happens there will be an amendment in the law which will be to our disadvantage.

THE CHAIRMAN Doctor Lester, I would like to ask you a question. Did this imply any extra cost to the insurance company?

DR. LESTER No, sir, because the patient was a resident of Seneca Falls and worked in Auburn.

DR. KALISKI I don't think there would be any question about that case.

THE CHAIRMAN I asked that question because it pulls the trigger on my own particular hobby, which is that the intimate personal relationship of doctor and patient is of more value than most people give it credit even in surgery. This man had a sense of confidence in going to his own doctor, his own surgeon, didn't he?

DR. LESTER Yes

THE CHAIRMAN Real confidence is worth a great deal

DR. KALISKI I think we have to look at this from a practical standpoint. I quite agree that a patient ought to be allowed free choice of a physician, but where somebody else is paying the bill I think we have to use common sense in the exercise of that free choice. On the whole it is found that the patient is not exercising the right of free choice to the extent that we would desire that he exercise that right. We are attempting to educate the public to the point of making them cognizant of the new law, the full effect of the new law on medical care, but at the present time we find that too many patients are waiving their right of free choice and willingly and gladly going to a physician selected by the employer

THE CHAIRMAN I won't crowd the point but I think it is interesting Any more questions, gentlemen?

DR. SUTTON, *Onondaga County* I want to ask under the circumstances about supplying the carriers with lists of qualified physicians with their accompanying symbols if they request them.

DR. KALISKI That is the reason we are doing this in the Directory. We had hoped to make some little revenue for the state society by the issuance of a complete list of qualified physicians for the entire state and to render the employers or companies an additional service by keeping the list up to date and to charge them for this service. We ascertained that a certain company last year offered to render this service at the rate of about \$50 a thousand names per year and to keep the service up to date. In other words, to make additions to the list as they were made by the county societies or changes in the list and to keep every industrial organization up to date on the list. We are in process of trying to negotiate this. I think that there is no reason why the county society should not make available to anybody who desires a list the names of all the physicians in the county who are qualified to render medical care under the new act.

DR. KALISKI May I say one further word? The question was brought up by Dr. Nelms. It is an important point and I would like to take a moment to consider it. That is the question of the amendment to the Workmen's Compensation Law. Under the old law the Industrial Board of the Department of Labor had the right to assess the cost of medical care and compensation against a non-insured employer. A great many non-insured employers are in business in the State of New York. Many employers allow their insurance policies to lapse. When injuries occur doctors treat the patients who are injured and find eventually that the risk is not covered by insurance. Under the amended act the Industrial Board has not the right or the power to assess the cost except in a case treated outside of the State or injured outside of the State covered

in the act. In other words, if a physician in New Jersey treats a case under the Workmen's Compensation Act the Industrial Board at the present time has the right to assess the costs against that employer if he is not insured and even if he is insured he has the right to do that under the present law. At the present time we are constantly receiving requests from doctors to get the name of the insurance carrier of a given employer. We ascertain that the reason that the employer doesn't give the name is that he is not insured. The only power that the Department of Labor has under the new law is the same power they had under the old law, namely, to proceed criminally under the Labor Law against such an employer for not being insured. He may be fined as much as \$500 and sentenced to prison. A number of such individuals were sent to prison in the last few months in New York City, but at the present time they have no way of assessing the cost of that against such an uninsured employer. This amendment is drawn up with the idea of giving the Industrial Board that power and I believe it is a good amendment. We are not anxious to have any amendments to this act for the fear that interested parties may slip in some other amendments not to our liking, but I believe this amendment is absolutely necessary.

(Dr. Lawrence called the roll of Secretaries and thirty-nine responded, this later being increased to a total of forty)

AFTERNOON SESSION

Address by the President

DR. WINSLOW, *Rochester* It has been my experience that the president of the county society takes a bow for a lot of good work that has been done by the secretary, and incidentally that also applies to the state society.

I will now try to just briefly discuss some of the current features of the work of the state society which are of most interest, although I realize that to a certain extent this is a repetition. I suppose probably the outstanding piece of work in which you are interested today is the question of pneumonia control. As a matter of fact, the study of pneumonia control started in the year 1917, nineteen years ago, and was a joint project of the state health department and the Rockefeller Institute. At that time our Dr. Lawrence was interested in the work of the state department and he presented to the county society the initial work which was done in the investigation of the cause of bacterial pneumonia, its typing, and an effort was made and was later successfully accomplished to bring out a curative serum.

The next matter in which you are interested is the question of syphilis control and that, as you all know, the Surgeon General of the United States, our own Dr. Parran, has recently made an appeal from the Federal authorities for the cooperation of not only the citizens but the medical men of the United States in an effort to prevent and wipe out syphilis, and that matter is of much interest to the medical society of the State of New York today. At the present time a sub-committee of the Committee

on Public Health is interested in and starting a campaign in an effort to wipe out syphilis. An announcement was made by one of the prominent lay agencies comparatively recently in which, in a letter which they sent out, they indicated that this lay agency practically intended to take over the control of cancer in New York State. That apparently has been tried before and it probably will be tried this time with no more success than accompanied it before. As a sort of an offset to that situation the Public Health Committee has appointed a sub-committee on cancer of which Dr. E. G. Whipple of Rochester is the chairman, and they intend to participate with the State Health Department in whatever effort is made along the directions of cancer investigation.

One of the other important matters under prosecution at the present time is the question of maternal welfare. You all know that some of the recent statistics have been rather appalling. An exactly similar action has been taken by the state society. A sub-committee of the Committee on Public Health headed by Dr. Quigley now has control of this work and is laying their plans for an efficient campaign which will be conducted during the coming year.

The next subject in which we are all deeply interested is the question of the JOURNAL of the Medical Society of the State of New York and that will be handled by Secretary Irving when he speaks directly following my talk.

As you heard from our very adroit and efficient Chairman of our Economics Committee, one of the things that confront the medical man in America today is the question of the political situation, and while we are essentially medical men and thereby barred from taking any public attitude in politics, we all still have our personal liberty which we more or less like to preserve. As you probably know, one of the senators from the State of New York has stated that if the present political regime is restored to power, one of their first acts will be the adoption of the Social Security plan including compulsory health insurance. Right here arises a question that makes you somewhat doubtful as to the power and the efficiency of organized medicine. The facts are, gentlemen, that of the physicians in the United States by and large there is just exactly one out of three that is sufficiently interested in exercising his elective franchise to go to the polls each November. Only thirty per cent of the doctors in America are so interested in this matter that they vote. It therefore behooves us to consider this situation with exceeding seriousness and to govern ourselves accordingly. Of course such a situation is fraught with imminent peril because the minute that the doctor steps from his position as a medical man over into politics there are many kinds of dangers which beset him. So it requires supreme judgment to act correctly in that situation.

As you also heard from our Chairman of Economics, one of the situations which face us is the question of our relations with the hospitals. It is a perfectly obvious situation that no hospital can exist without doctors. It is almost equally true that the doctor has to have

the hospital. I have talked with some of the authorities in the New York State Hospital Association and they are very frank and very square in admitting that during the stress of the recent economic crisis some things have crept into the hospital practice which they deeply regret and which they feel are not quite right, and they welcome the opportunity of sitting down with duly appointed committees of doctors and discussing these problems in a constructive effort to solve them. I believe that during the coming year we will reach an amicable settlement of a large percentage of the problems which today affect jointly the hospital and the doctor.

I suppose no good speech could be complete without making constructive suggestions as to how to conduct yourselves. I had a little shiver run down my spine just before the meeting when one doctor walked up to me and said he had been a member of a state society forty years and secretary of the county society for thirty years and I am pretty skeptical that I could tell him very much about how to conduct himself. However, if I may point out some suggestions I would like to take up four things.

One, the matter of records. I suppose a county society secretary gets fed up on the matter of keeping records. At the same time there are numerous occasions that arise when the well-kept records of the county society are of very great importance to our headquarters in New York City and we appreciate the fact that in the main you keep good records and urge that if possible even a better job could be done in this direction. One way you can be helpful is this. With the incoming administration each time please see to it that the committees are appointed promptly, that there won't be any lapse between the two administrations, and as soon as committees are appointed, please see to it that the names of the chairmen of the committees at least and the names of the members, if possible, are reported to our headquarters in New York.

The second is the question of membership. Last year the American Medical Association increased their membership by 2,000 men and of the 2,000 additional memberships in the American Medical Association, much to our pride, 1,000 of them came from New York State. That means that New York added as many members to the American Medical Association as all other states combined last year. It is also quite obvious that within the districts from which you come there will be some physicians whose membership in your society may be undesirable. However, I beseech you to see if possible that a membership committee is appointed in each county society whose duty it will be to canvass the physicians who practice in that community and to secure from them the applications of those who are desirable, which may be added to the list of membership in the state society.

The third point I wish to emphasize is the desirability of your close contact with our headquarters in both New York City and Albany. There are many things that come up which make it helpful in both ways, both to the head-

quarters and to you, in arranging the programs for your society. You can receive almost invaluable aid either from our Bureau of Public Relations headed by Mr. Dwight Anderson, from the Committee of Trends, headed by Dr. Townsend, from our Secretary, Dr. Irving, or Executive Officer, Dr. Lawrence. They also profit by knowing what your programs are. So, conversely it is equally interesting for you to send to them the details of each one of your society meetings. Another exceedingly important function of the state society at the present time is the postgraduate lectures. These are under control of the Public Health Committee headed by Dr. Farmer, and in case you desire any information in connection with holding such a course he will be more than glad to communicate with you.

The fourth and probably the most important matter of interest is the question of attendance at this meeting. The efficiency of the work of each county society in the state has been greatly facilitated since these meetings have been held. I am sure that this is the most helpful one that has been held. The work is very much appreciated here and it is bound to advance the interests of the society.

Gentlemen, the ability of the Medical Society of the State of New York to form an efficient program is dependent upon the interest and the support which it receives from the officers and the members of its county societies. I congratulate you upon your attendance today, upon the interest which you show in your work, and I hope that you will pass the word around so that next year you will have even a larger percentage of attendance. And as you go from here I hope you will bear in your minds three things.

First, I hope you will go forth fully sensitized to the desirability of the advancement of the projects which are discussed here today.

Second, I hope that you bear very deeply in your minds the desirability of being dissatisfied with any secondary accomplishments either in your personal efforts as secretaries or in the efforts of your societies.

Third and last, I hope that you will fully realize the importance which rests upon a realization of a physician that it is his duty to give to the citizens of New York State the utmost, the very best medical care. Thank you.

REMARKS OF DR. IRVING, *Secretary*. For the first time in the last three years, I have felt free to give the JOURNAL a bit of a boost in speech. If I may be a little personal for the moment, the daily running of it fell into my lap without my seeking it at all some two and a half years ago, and my first sensation was that I was quite adolescent. It was like running a school paper in a prep school. Nevertheless we went to work and we have gradually increased the magazine in size. You had ninety-six pages during the summer. This last issue was 128. The next will be the same and on the first of October it will be 160 pages. That is going to make it possible for us to open up a lot more news features, news that covers a great many things in which the doctors are

all interested such as hospital news, medical school news, and to give to each one of these major items a heading at the top of the page, so that you can find them in successive numbers. I feel very much encouraged over the outlook for the JOURNAL.

The hooking-up of the county societies and the State society is partly accomplished through our column known as Medical News. It comprises news not only of county societies' activities from the county societies but also of other news that comes from that locality. We have never found yet a very satisfactory way to fill that particular column. At first we tried to get it from the secretaries individually and a few came across very nicely, but in the main there wasn't very much to be gotten. We very early decided we couldn't publish minutes as minutes. They are very dry and do not mean much except for reference. They can, however, be put in narrative form very often and be quite interesting.

Then we found a way to get more news from newspaper clippings, written by newspaper reporters. They had a news value, in news form, but they have a great defect in that they are inaccurate, and it is difficult for us to check on those inaccuracies, and sometimes we have funny little mistakes and errors that come out in the JOURNAL, and we can only regret them. I think that if all the county societies represented here, and I hope all the rest of them, would establish the custom of sending either directly to me—I should say preferably now directly to me rather than to the JOURNAL office, as you have been asked, a few of you, to do lately—directly to me at the State Society office, it will serve two purposes. Not only will it give us more information from the county societies for the JOURNAL but it will also help to accomplish an ambition that I have had in the back of my mind for some years. That is a closer knowledge of the problems of the county societies in the State office. That fits with coordination of effort and action between the sovereign units, the county societies, and the State Society that sits in a position of helping. So that I hope you will take that back from this particular meeting, all of you, and I hope that we will see enough of each other in the coming years so that we can make that even more useful.

DR. LESTER. That is 2 East 103 Street?

THE CHAIRMAN. Correct. There are many complaints that will come into the JOURNAL. One gets them from time to time. Why did you print that? What do you mean by printing this? I don't object to that. It proves to me one thing beyond all others, that the men are reading.

(Dr. Townsend, chairman of the Committee on Trends then described the work of his committee and Mr. Anderson, Director of Public Relations of the State Society, amplified with details. This portion of the remarks is on file in the Secretary's office.)

Remarks by Dr. Mitchell, Chairman, Committee on Revision of Constitution and By-laws. I won't detain you long, because I know

you are very tired or worse, and you are probably anxious to get through with today's activities. In these days with our compact society it seems as if a great many minds are turning to the question of the revision of instruments that we call constitutions, and I wouldn't be surprised that future historians might call this a sort of an era of constitutional monkey business. So it isn't surprising that we have called to our attention that we should give some thought to our constitution and by-laws, whether or not we might better in some way the management of our organization.

Last year a special committee advised Dr Gordon Heyd and studied the constitution and by-laws, the question of consolidation of executive offices, and reported to the House of Delegates. The report is to be found in the JOURNAL of June 15, 1936, Section 9 and 71 on the consolidation of executive offices. If you have not read that, I think you should do so and study it very carefully.

As a result of that report, the House of Delegates appointed another special committee, of which I happen to be the Chairman, known as the Committee for the Revision of Constitution and By-Laws. We haven't any set ideas as to just what we are going to recommend. There are a considerable number of recommendations in this original report. We will study these, and will listen to suggestions from members of the society from all parts of the State. I can assure you that we will not do anything radical. We will not do anything unless the majority of the members of the society want the changes to be made. And so we are busying ourselves with that investigation and study.

The members of the committee are Doctors Goodrich, Cunningham, O'Gorman, Mott, and myself. Of course, we are consulting with other officers and various individuals of the Medical Society and in various parts of the State.

Let me ask that you read what is in the JOURNAL as a part of the minutes of the House of Delegates. Go over it carefully. If you care to, give us some suggestions which may prove to be very helpful. Don't hesitate to do so. We will welcome them and get in touch either with the Chairman or any member of the committee or if you want to send to Dr Irving or anybody else, so that they will eventually clear through our committee. We hope to be able after studying and working at this problem, to submit a report at the next meeting of the House of Delegates, making some suggestions or perhaps quite a complete outline of what we think should constitute the constitution and by-laws of the Medical Society of the State of New York. Thank you.

DISCUSSION

DR. ROONEY. I am very interested to hear the report of Dr Mitchell, particularly because I think that it is one of the most important committees that this society has constituted within the last fifteen to eighteen years. If all of us will recall certain of the proposals

that were made by the Committee on Reorganization of the State Society and they were, to say the least, in my opinion, startling, because they practically converted the society over from a democratic body ruled by the House of Delegates to, essentially, a rule by a group of officers with long terms of office and very difficult to displace. In effect, the large controlling committee was to be composed, essentially, of men whose terms of office ran for three to five years and approximately a little over a majority of that group were not elected. The House of Delegates was converted or would be converted by that sort of plan nearly to the very present position of the present German Reichstag. Now I am more than pleased to hear Dr Mitchell say that he wants to have suggestions and proposals from all of the various members who are interested in this, and I think we all must be interested, and I merely wish to offer this suggestion, having been a member of the last Committee on By-Laws, the last Committee on Revision of the Constitution and By-Laws, of which to the best of my recollection Dr Heyd was Chairman and I was Secretary, and we held hearings. We held three hearings throughout the State in the various districts. During the course of those hearings, the members and societies had the opportunity of coming before the Committee and presenting their recommendations completely, not merely by letters or indiscriminately, but these hearings were held far enough in advance so that any member or officer of the society who desired to make certain recommendations to the Committee would have the opportunity of doing it *viva voce*. I think that at least, and I am expressing merely my own opinion, that I am entirely in concurrence with what Dr Mitchell has just said about the fact that we are in an epidemic of monkey business about constitutions and by-laws and government. Really we are becoming, and I am in hope that the profession will not be infected by it, the whole world apparently seems to be like a group of monkeys in a cage, long-tailed monkeys, each successive one holding on to the tail of the preceding one, finally constituting a complete circle, and all of them going through a very lovely, beautiful dance and mistaking motion for progress.

Now it seems to me that it is about time for us to sit down, take thought about just exactly what we want to do about this constitution and these by-laws, which it seems to me have worked very well, except for minor changes perhaps that have to be made evolutionary. To make a complete change in the status of the representative government of this profession, convert it into a sort of Fascism or oligarchy or whatnot, it seems to me at least is not called for. I present these to you because I feel very keenly about it. I feel that it is one of the ways that the profession will not evolve but will retrograde and it is of course a part of the scheme of the times, not alone abroad but also in America and I think it is like many others, the other schemes of government, the proposals for changes in government, which historically are not new, are not forward looking, but in every

instance are retrograde to the primary thought of tribal savage Communism

THE CHAIRMAN If I remember the minutes of the House of Delegates correctly the Reference Committee advised that such hearings be held. Dr Lawrence, have you anything more to say?

DR. LAWRENCE May I be permitted to express my appreciation of the cooperation that I have had with the Secretaries, and also to congratulate you, Mr Chairman, upon the great turnout that we have had today. This is the best turnout of Secretaries we have ever had in the years that I have been connected with the Society. We have tried hard and I believe that it indicates that there is a more lively interest from the county societies in the county societies, than ever before.

May I ask now that in support of what Dr

Irving has said to you that when you need assistance you have two offices, one in New York City, and the other in Albany? Don't hesitate to write to either of us to help in any way we can. Dr Irving and I are both going to visit the county societies as much as we can. We want to do all we can to encourage and develop the individual county societies. We have seen its effectiveness in our legislative work and it can be just as effective in our public health work, economic work, and other fields that are yet to be developed, and especially too now that we have this very efficient agency, our Public Relations Bureau. Don't hesitate at all to give us an opportunity to be of assistance where we can.

THE CHAIRMAN Gentlemen, the wheels are greased. Whatever you tell Dr Lawrence he will tell me, and whatever you tell me I will tell him.

WORKS PROGRESS ADMINISTRATION—INFORMATION

Announcement by The Committee on Economics

Physicians of the State are advised by Mr C M Whipple, State Compensation Officer of Works Progress Administration, that bills and reports of the care of injured W.P.A. workmen should be mailed to the office from which the authorization originates and not to Washington. Communications sent to Washington, particularly the initial reports, will occasion a search for previous records and a long delay and perhaps the record is lost, whereas if it is sent directly to the local office the administrative handling of the case should proceed without delay or fault.

Until further notice the attention of the medical profession is directed to the fact that the Works Progress Administration requires a report from the physician every two weeks on the care of injured workmen. These follow-up reports need not be extensive and should include the identification of the patient, the date of accident, and a brief note of developments during the preceding two weeks. Some physicians may

complain that "here is some more of that paper work." May we direct their attention to the fact that progress notes are required in all good hospitals and this is nothing more than such a performance and we recommend that those physicians who do not want to trouble themselves to make this cooperation with the Administration should decline to treat these cases.

When physicians render medical care to injured W.P.A. workmen, no matter what the character of that care may be—x-ray, pathology or otherwise—the doctors should render bills for such services from their homes and not from the hospitals. This will avoid confusion as to the relationship of the hospital to the medical care. Where there is a question of proration of fee between the doctor and the hospital that is a matter of arrangement outside of the domain of the Works Progress Administration. They will pay one fee for the service.

September 9, 1936

DOCTORS FEES LIKE TAXI FARES

A hundred years ago practicing physicians in New York City and other Eastern communities charged by the mile, like modern taxicab drivers, according to Dr Henry Burnell Shafer, whose book, "The American Medical Profession, 1783 to 1850," is reissued by the Columbia University Press.

In Lowell, Mass., for example, the standard charge for treating patients at home was seventy-five cents for the first mile and

forty cents for each additional mile, with a surcharge of twenty-five cents a mile for night trips.

Dr Shafer's research discloses that in those days New York surgeons charged \$50 for amputation of a limb, \$10 for amputation of a finger or toe. Bleeding charges were — By cupping glass, \$5, at the arm, \$2, and at the jugular vein, \$5.

WORLD'S FAIR

The Big Fair as a Medical Show

Plans for a great health center and permanent public museum of health and hygiene for the New York World's Fair of 1939 are announced with the formation of an advisory group representing city and national health and medical organizations.

In making the announcement, Grover Whalen, President of the Fair Corporation, said that health and medical science will be ranked as one of the most important phases of the Fair. Plans for the necessary buildings and exhibits are yet to be worked out, but both the Oberlander Foundation and the Carnegie Corporation have already pledged financial aid. Other grants are expected to provide a fund for retaining the exhibits as a nucleus for the permanent museum.

The committee, of which Dr. Louis I. Dublin will be chairman, will undertake a five-fold project involving the establishment of a permanent museum of hygiene such as the famous German institution at Dresden.

The five major objectives as announced are:

1. A complete coordinated health and medical exhibit, illustrating for public education the results of medical research, which would furnish during the Fair a nucleus for a large group of commercial exhibits of products related to health and afterwards the nucleus of a permanent institution.

2. A model health village constantly demonstrating equipment and methods in daily use by individuals, families, and communities.

3. Emphasis at every appropriate point throughout the Fair of protective devices and services installed for the benefit of the visitors, which illustrate with commercial advantage the value of the device.

4. Provision for a permanent health center.

5. A strict censorship of medical products and other things sold or promoted on a health basis.

The makeup of the committee is as follows: Chairman, Dr. Louis I. Dublin; Vice Chairman, Dr. James R. Reuling; Secretary, Mr. Homer N. Calver.

For City of New York: Dr. John L. Rice, Commissioner of Health, and Dr. S. S. Goldwater, Commissioner of Hospitals.

For Medical organizations: Dr. George Baehr, New York Academy of Medicine, Dr. James R. Reuling, American Medical Association, and Queens County Medical Society.

For Public Health: Dr. Victor Heiser, chairman of the General Council on Medicine and Public Health, Dr. Louis I. Dublin, National Health Council, Mr. Homer N. Calver, American Public Health Association and allied groups.

A larger general committee will be formed later to give representation to numerous organizations that may have something to contribute to the exhibits.

Activities of the committee are already well under way. Dr. Dublin has sailed for Europe, and while abroad will work to interest health and hygienic organizations in holding congresses in New York during the World's Fair period.

Secretary Calver has just returned from abroad, where he spent eight weeks visiting health museums and expositions to seek material for inclusion in the exhibits here. He brought back more than fifty exhibits from Germany, France, and England for consideration of the Fair committee.

The medical center and exhibits are being planned, it was explained by President Whalen, with the aim of presenting "the material, social and professional equipment now available to society for its health protection and promotion, and to provide a dramatic visualization of the brilliant possibilities for a humanity fully served with these facilities."

"Public health and medicine are deeply concerned with the future of individuals and the race. Their objective is aptly phrased by Dr. Dublin in the statement, 'If we could apply the knowledge we possess we could add ten years to the average life expectancy in America.'"

The health and medical exhibits, it was pointed out in Mr. Whalen's statement, will tell simply of the relation of the exhibits to the individual, with man himself as the central motif. In the exhibit, it is planned to have representations of:

"Models of the human embryo in its various stages of development.

"Formation of habits, nutrition, and other problems of bodily and mental development in the early years of life, illustrated with common examples which the visitor may recognize from his own experience.

"Protective devices in school and playground, discovery and correction of defects, organization of the school for health and health teaching, posters, models, plays and programs prepared by the children themselves, would visually demonstrate the beginning of participation by the individual himself in his own health protection and promotion.

"Men and women in adult life, their hazards of occupation, personal hygiene, periodic examinations, accident prevention, responsibilities of parenthood, typical prob-

lems illustrated here with moving devices, and mechanical demonstrations will carry along the dramatic story of man's inward struggle to survive and prosper in his modern environment

"A considerable section of the exhibit will be devoted to the early recognition of degenerative diseases, such as heart disease, cancer, nephritis, and diabetes. The fact that much may be done to prolong the lives of those who suffer from these diseases should alleviate the mental strain and stimulate sufferers to avail themselves of the skill of surgeons, the benefits of x-rays and radium, the relief afforded by insulin, etc

"Dominating this section of man himself and visually summing up the health story of his life may be a life-size man, woman and child, all transparent (as was the transparent man at the Century of Progress) naturally posed and inwardly illuminated to furnish a brief lesson in gross anatomy and surrounded with working models of the heart, the lungs and other organs, so that the visitor can see 'how the wheels go round' and thus better understand the care of his own body

"Why do some people get sick and some stay well? The question of immunity affects all age groups. A special section of the exhibit may be set aside to deal with this little understood problem. What we know about immunity, how it may be acquired naturally and artificially, its possibilities and limitations. This story has never been told wholly and understandably to the public. Working models showing the reactions of toxin and antibodies as they are now understood will provide a sympathetic understanding for immunization and vaccination services"

Other subjects to be included are

Air hygiene and ventilation
Nutrition and the food supply
Water purification and sewage disposal
Municipal cleansing
Noise—its cause, effect and prevention

Mental hygiene—what it is and how it serves
Epidemiology and the disease detective
Protein poisoning—the ragweed and its allies
The sagas of the Health Heroes of History
Quacks, Quackerv, Nostrums, Fads and Fallacies

Superstitions—old and new—Relics of the Medicine Man

"It should be pointed out," Mr Whalen continued, "that these proposals for the exhibit are definitely related to plans for the establishment of a permanent national museum or similar institution devoted to mass education in health, situated in New York on the Fair site or elsewhere. Such an institution has abundantly demonstrated its value in Europe and it is believed that with such a permanent goal the development of the health and medical exhibit at the World's Fair would be immeasurably facilitated

"In addition to these proposals for the health and medical sections of the Fair, there are other related matters contributing to the success of the Fair to be considered

"For example, a model American community constructed and operated under expert health guidance would be interesting and instructive. Here in model homes, built with constant attention to details which affect the health of the occupants and equipped with every device which modern industry affords for health protection, a selected group of people trained to observe health rules, would live during the Fair. By signs or otherwise attention would be called to health protection devices and practices in homes and shops and stores. This would be a constant living demonstration of personal, family and community health, which at the same time would offer opportunity for a display of reliable, commercial products in use.

"A further and most important consideration is that all phases of the Fair be developed and operated to assure the maximum health protection to Fair visitors and workers"

THE BIGGEST PUBLIC HEALTH MENACE

With one-tenth of the entire population of the United States already infected and with one-fourth of these persons doomed to chronic invalidism or death, syphilis presents itself today as the greatest public health problem in the United States, according to Dr Joseph Earle Moore, Director of the Syphilis Clinic, Johns Hopkins Hospital, in an address at the annual convention of the State and Local Committees on

Tuberculosis and Public Health at the Hotel Biltmore, New York City

In its effort to aid in the treatment of patients infected with syphilis, the State of New York has now extended its free distribution of arsenical and bismuth preparations used in the treatment of syphilis to physicians throughout the State without charge, and without reference to the financial condition of the patient, Dr Ramsey told the convention.

THE PHYSICIANS' HOME

Encouraging progress is reported in the campaign to raise an endowment for the Physicians' Home. Dr. Charles Gordon Heyd, president of the corporation, announces that contributions are coming in daily in response to a recent mail appeal sent to the physicians of the state, but that funds are still inadequate to meet the need.

"A present," says Dr. Heyd, "we can only care for six guests, and have many fine men on the waiting list."

The appeal for funds sent the physicians of the state is an urgent request for assistance in taking care of members of the profession.

"Sir Ronald Ross," states the circular, "after long years of research, revealed the cause of malaria—thereby honoring his profession and himself—and adding untold millions to the wealth of the world."

"But Sir Ronald, when old and poor, still had to labor for his daily bread."

"It is to men of the stamp of Sir Ronald Ross—those who have done their best, according to their abilities—that we should like to offer a home when the time comes for them to rest, deservingly without worries. The Physicians' Home represents the effort of a group of physicians to open up the way."

"Founded in 1918, it has existed through the years on a modest scale. But the whirlwind of a national depression has left in its wake the stark reality that this 'modest scale' is shamefully deficient."

"Recognizing the tragedy—particularly to many older colleagues—that economic conditions are bringing, the Physicians' Home has been reorganized, the Board of Directors enlarged, new officers elected, and a fresh impetus established, namely, to create

an adequate home where distressed but worthy members of our profession will be offered comfort and companionship, together with our full esteem.

"They are men who would not care to go to a local or state institution. They are men, like the aged physician of good standing who wrote, 'On account of my physical condition I am slipping back and finally will have to join the great number of professional people with poverty before them and no home to which I can go. It is not the case yet, but how I fear it! If it should be, I cannot live any longer.' This physician would be too proud to make an appeal to a state or local fund, but will gladly become a guest of the profession, and has received our invitation to come to us when he is ready."

"At present the Physicians' Home is limiting its field to New York State. We are urging you, as a New York physician, to give us whatever help you can, either by becoming a Member, a Patron, or a Benefactor—or by enlisting the sympathetic cooperation of grateful patients and other non-medical friends of the profession. Annual Member, \$10 or more, Sustaining Member, \$100 to \$1,000, Life Member, \$1,000 to \$5,000, Patron, \$5,000 to \$10,000, Benefactor, \$10,000 or more."

Make the check payable to the Physicians' Home and mail it to Dr. B. Wallace Hamilton, treasurer, 52 E. 66 Street, New York City.

Officers of the Physicians' Home include Dr. Charles Gordon Heyd, president, Dr. Warren Coleman, 1st vice-president, Dr. Silas F. Hallock, 2d vice-president, Dr. B. Wallace Hamilton, treasurer, and Dr. Joseph J. Eller, secretary.

PUT DRUGS UNDER LOCK AND KEY

The State Health Department has warned doctors and other narcotic dealers in New York State to keep their supplies "under lock and key to prevent further thefts by addicts."

The warning is made, the department said, as the result of two recent thefts in the Albany area, one from a physician's office and the other from an institution.

"A big step can be taken in the promotion of public health and improved social conditions if all of these persons who legitimately handle narcotics will comply with this warning and prevent the addict from securing these drugs," Frank J. Smith, supervisor in narcotic control in the department, said.

"The ease with which one theft was committed by a floating drug addict who came to this state from an outside community and secured the narcotics has a particular interest to all of us. This instance, not uncommon, draws attention to the need for safe storage of narcotics and for maintenance of accurate records regarding the dispensing of such drugs by physicians and pharmacists."

"In this particular case the physician had no knowledge of the loss of the tablets until their identity had been traced by the department through the manufacturer and then reported to the physician."

Medical News

Secretaries of County and local Medical Societies are requested to send the programs of coming meetings to this department one month in advance, for the information of members who may be interested

Allegany County

DR EDWIN F COMSTOCK, of Wellsville, Secretary of the Allegany County Medical Society, reports that the quarterly meeting of the society will be held in Belmont on October 29 Officers will be elected

Cayuga County

DR C H MAXWELL of Auburn reports that on September 24, Dr Russell H Cecil gave a postgraduate lecture, as arranged by the State Committee, on Chronic Arthritis and that other lectures will follow, to be delivered at 8 30 P M sharp at the Auburn City Hospital on the following schedule

Oct 1 "Significance of Laboratory Tests and Methods", Dr Ralph Stillman, New York City

Oct. 8 "General Aspects of Abdominal Surgical Diagnosis", Dr Edward Livingston, New York City

Oct. 15 "Physiology of Kidney Diseases", Dr William Goldring, New York City

Nov 19 "Legal Relationship Between Patient and Physician", Lorenz J Brosnan, Esq., (to be read by Mr Thomas H Clearwater, Attorney to State Society)

Columbia County

DR. FREDERIC C HARGRAVE, President of the Medical Society of Columbia County, has written a letter to Dr John R. Ross, President of the Medical Society of Dutchess County, complaining that some of the Dutchess doctors are "underbidding" Columbia county doctors in the matter of children's health examinations as ordered by the State Department of Education

"I am writing you so that you may know what we are doing on our side of the line and to ask if we might be favored with a little help from Dutchess county," the letter reads

"We are running into a little difficulty along our southern border because some of the men on your side of the line are underbidding our men in the matter of these health examinations

"In fact they are offering to do them for \$ 50 a child.

"We, in this county, do not feel that in this effort to make an examination of the type wanted by the State Department of Education that we can afford to do them for less than \$1 as it takes approximately 15 minutes for each child if the outline is followed.

"I did not know but what a communication from you to these men along your northern border would help to keep misunderstandings in this matter from arising"

Dutchess County

A SPECIAL PROGRAM of motion pictures was shown at a meeting of the Dutchess County Medical society at the nurses' home, St. Francis' hospital, on Sept. 9

The pictures included the Diagnosis and Treatment of Infection of the Hand by Dr Allen B Kanabel of Chicago, and the Treatment of Burns by Dr Grover C Penberth of Detroit

The discussions were opened by Dr J E Sadlier and Dr Moffit of this city

Erie County

DR. LOUISE W BEAMIS, Secretary of the Medical Society of the County of Erie, reports that the next stated meeting of the Society will be held October 19 The meeting will be devoted to committee reports, chiefly workmen's compensation and maternal mortality, with discussion of the work done since the May meeting

Franklin County

DR. LEONARD ROWNTREE, of Philadelphia, gave an address on "Hypertension" on Aug 26 at the John Black Room, Saranac Lake, before the Saranac Lake Medical Society and visiting physicians and medical students

Jefferson County

DR C A. PRUDHON, Secretary of the Medical Society of Jefferson County, reports that the next meeting of the society will be held October 8 at the Black River Valley Club, Watertown

Kings County

THE NEXT MEETING of the Medical Society of the County of Kings will be held Oct 20 in the MacNaughton Auditorium, 1313 Bedford Ave., Brooklyn.

Lewis County

DR. F E JONES, Secretary of the Lewis County Medical Society, reports that the annual meeting will be held on the second Tuesday in October, the 13th, at Lowville

Monroe County

DR. MILTON VAN HORN, seventy-two, Churchville physician for more than forty years, died Aug 25

He was born in Register, Pa, Nov 30, 1863, and was graduated from the University of Pennsylvania in 1891, going to Churchville in the late summer of the same year to practice his profession

Eight years ago, failing health forced retirement for Doctor Van Horn, who in his younger days had been known to exhaust four or five horses in making the rounds of his numerous patients

Actively interested in civic problems, Doctor Van Horn served on the Churchville Board of Education for twenty years

DR A P MAINE, aged ninety, oldest practicing physician in Monroe County, was the guest of honor at a clambake at the Webster Presbyterian Church on Sept 17

New York County

THE NINTH ANNUAL GRADUATE Fortnight of the New York Academy of Medicine to be held October 19 to 31 will be devoted to consideration of trauma, occupational diseases and hazards

Twenty-three important hospitals of the city will present coordinated afternoon clinics and clinical demonstrations. At the evening meetings prominent clinicians from various parts of the country who are recognized authorities in their special lines of work will discuss various aspects of the general subject. A comprehensive exhibit of books, pathological and research material, apparatus for resuscitation and other first aid appliances will be assembled. Demonstrations will be given at regular intervals

Among the topics to be presented at the meetings, in the clinics and in the exhibit will be first aid in industry, in the home and on the highway, accidents and their management, burns—thermal, electrical, radiant and chemical, medicolegal aspects of trauma and disability, carbon monoxide poisoning, fatigue and noise in industry, harmful conditions in industry, industrial poisonings, and relation of trauma to disease

The medical profession is invited to attend. A complete program and registration blank may be obtained from Frederick P Reynolds, M D, The New York Academy of Medicine, 2 East 103 Street, New York City

THE SEVENTH CLINICAL SESSION on chronic pulmonary diseases, under the auspices of the Tuberculosis Sanatorium Conference of Metropolitan New York, will be held in the amphitheatre at the Cornell Uni-

versity Medical College, at 1300 York Ave, 69th-70th Sts, Wednesday evening, Oct 7. For further information communicate with Bernard S Coleman, Secretary, 386 Fourth Avenue, New York City, Caledonia 5-2240

DR. WILLIAM HALLOCK PARK, who collaborated with Dr Hermann M Biggs in developing a successful diphtheria antitoxin, and Dr Harold Dickinson Senior, eminent research scientist in the field of embryology of arteries and veins, have retired from the faculty of the New York University College of Medicine after a total of sixty-four years of teaching service.

DR JOHN WINTERS BRANNAN, a general practitioner of medicine in New York for half a century and formerly for twenty-one years president of the board of trustees of Bellevue and Allied Hospitals, died on Aug 30 in the Polyclinic Hospital, after a year's illness, at the age of eighty-three.

Dr Brannan was largely instrumental in bringing about the reorganization of Bellevue and its allied hospitals, providing new buildings for them and raising their standard of medical treatment

From 1902 to 1923 Dr Brannan was president of the trustees of Bellevue and Allied Hospitals. He was appointed to the board by Mayor Low after he played an active part in obtaining an amendment of the city charter which removed the hospitals from the Department of Charities and provided for their reorganization under a board of trustees

During his long service as president of the trustees new buildings were provided for Bellevue and its allied hospitals, Gouverneur, Harlem and Fordham. A separate psychopathic department was established at Bellevue, appointments to the medical boards of the hospitals and the system of medical and surgical directors were reorganized to insure continuity of service, and the Bellevue Hospital School for Midwives was established

An authority on tuberculosis, Dr Brannan secured the opening of the first fresh-air classes for under-nourished or tubercular pupils in the public schools in 1910 and was instrumental in establishing the Neponsit Beach Hospital for Children on Long Island.

While in the last several years Dr Brannan had not been in active practice, he was at his death consulting physician at Bellevue, Polyclinic, Ruptured and Crippled and Willard Parker Hospitals and a member of the medical advisory board of the Department of Health. He was trustee of the New York Infirmary for Women and Children and member of many medical societies

Niagara County

DR. C W GEORGE, of Lockport, Secretary of the Medical Society of the County of Niagara, reports that the next meeting will be held on Oct. 13 at the Niagara Hotel Niagara Falls. Dr Russell L Cecil, of New York City, will speak on "Pneumonia"

Oneida County

DR. JAMES IRVING FARRELL, Secretary of the Medical Society of the County of Oneida, reports that the next meeting will be held on Oct. 13 at "Broadacres," the Oneida County Tuberculosis Sanatorium. It will be a luncheon meeting.

Ontario County

DR. J W HOWARD, of East Bloomfield, was host on Sept. 10 to the Canandaigua Medical Society at the first Fall meeting.

Dinner was served, followed by the business session and a paper by Dr J R Honiss, of Rochester, Summer resident of the West Lake shore, on "Nasal Ionization Treatment of Hay Fever."

Orange County

STRESSING THE POINT that it took only \$50 to start the project, Dr Joseph N Bellino, town health officer, won his petition for a health center in New Windsor at the Town Board's meeting in Vail's Gate on Sept. 8, says the *Newburgh News*.

Dr Bellino explained that he proposes to use the old New Windsor railroad station as a clinic until conditions warrant that such a station should be placed in a more congested part of the town. He pointed out that \$50 would suffice to prepare the station for the clinic which will take care of children in the preschool ages between six months and five years.

Labor for renovating the station and funds for equipping the clinic have been promised by taxpayers.

Rockland County

THE FIFTH ANNUAL clambake of the Rockland County Medical Society, held on September 9 in the grove at the county sanatorium at Summit Park, was marked by the presence of distinguished guests. It was one of the best affairs ever given by the medical profession and was largely attended, according to a report sent in by Dr William J Ryan, of Pomona, Secretary.

Guests of the county doctors included Dr Floyd S Winslow, of Rochester, president of the Medical Society of the State of New York, Dr Joseph S Lawrence, of Albany, executive officer of the society, Dr Eugene W Bogardus, of White Plains, director of

the Division of Tuberculosis of the Department of Health of Westchester County, John B Kelly, superintendent of the New York Reconstruction Hospital Home at West Haverstraw, Dr Oswald R. Jones, Dr Frank B Berry and Dr James W Smith, all of New York City.

In addition there were present Dr George A Leitner, president of the Board of Managers of the sanatorium and three members of the board, Dr John Sengstacken of Stony Point, Dr George J Vieth of Suffern and Alfred Miller of Haverstraw.

St Lawrence County

DR. DAVID M. FOSS, seventy-six, a practicing physician at Gouverneur for the past 36 years, died at his home on Sept. 8, after two weeks' illness.

During the thirty-six years that Dr Foss had his office in that village, he became a familiar figure throughout the wide section of the north country, says the *Watertown Times*. The weather was never too cold, nor the snow too deep, nor the distance too far for him to start out at any hour of the day or night. In the days before automobiles, he had three drivers who were kept busy day and night carrying him all over St. Lawrence county with a horse and buggy or cutter.

At one time Dr Foss was making trips to fourteen towns adjoining Gouverneur to call on his patients, according to Mrs Foss. In the past few years of his practice, Dr Foss became well known for his success in the treatment of eczema and other skin diseases. Patients have come to consult him on these diseases within the past two or three years from about twenty-four states and from Canada. They have come from all the eastern states and from as far west as Indiana and Illinois.

Schenectady County

DR. ARTHUR Q PENTA, of Schenectady, told the 14th Congress of French-speaking Physicians of North America in Montreal on Sept. 10 that smoking has increased the number of asthma sufferers among women. Dr Penta heads the bronchoscopic clinic at Schenectady City Hospital.

Seneca County

DR. FREDERICK W LESTER, Secretary of the Seneca County Medical Society, reports that the semi-annual meeting will be held October 8 at the Willard State Hospital, Willard. The scientific program will include a paper by Dr A W Sohrweide of Syracuse, on "Some everyday problems in the treatment of diseases of the skin", and a clinical demonstration of "Some forms

of mental disease", given under the direction of Dr Harry J Worthing, superintendent of Willard State Hospital, by some member of his staff. A mid-day dinner will be served in the hospital by the invitation of Dr Worthing.

Steuben County

DR C E PATTI, physician, and Dr Porter Sweet, dentist, have consented to donate their time for an evening each week to teach courses in personal health and disease prevention in the Adult Education night school in Hornell sponsored by the State Department of Education and directed by Francis J King.

The course will be part of the program to enlist prominent professional persons in Hornell to donate their time for instruction in the night school as new features in addition to the regular curriculum. A similar set up is being designed for twelve other Steuben communities, Bath, Corning, Wayland, Hammondsport, Pulteney, Woodhull, Canisteo, Arkport, Atlanta, and Cohocton.

Sullivan County

DR DEMING S PAYNE, of Liberty, Secretary of the Medical Society, County of Sullivan, reports that the annual meeting and election of officers will be held on October 14.

Warren County

DR MORRIS MASLON, Secretary of the Medical Society of the County of Warren, reports that the annual meeting will be held on Oct 14 in Glens Falls. It will be mainly a business meeting.

Washington County

DR S J BANKER, of Fort Edward, Secretary of the Medical Society of the County of Washington, reports that the annual meeting will be held at Hudson Falls on Oct. 6.

Westchester County

INTERESTING ITEMS of news from the hospitals of Westchester County are contained in the *Westchester Medical Bulletin*.

Lawrence Hospital, Bronxville, has just completed a rather extensive program of renovation. The X-ray department has been removed from inadequate quarters in the basement to commodious rooms on the second floor. A number of new units of X-ray equipment have been purchased, and a pleasant waiting room for the department has been provided. Three new semi-private rooms of two beds each have been added, and in the out-patient department new clinic rooms have been opened. There have also been extensive alterations in the wards, giving increased light, the accident

room has been relocated and enlarged, store room space has been expanded, three new electrically heated food conveyors have been acquired, and an incinerator has been built in the basement with openings on each floor.

The hospital's main entrance has been completely changed to give a more spacious appearance, and great changes have been made in the grounds surrounding the hospital.

A new electrocardiograph has been purchased and a room is now being equipped for electrocardiograph and basal metabolism examinations.

Miss Grace C Schmiedel, who has been connected with Lawrence Hospital for a number of years, was appointed Assistant to the Superintendent. Miss Antonie Reuter, who for over ten years was in charge of the nursing in the Private Pavilion of the Lenox Hill Hospital in New York City, was appointed Director of Nursing on July 1st. Dr Robert P. Sim, Dr William T. Doran, Jr., and Dr L. C. Gerlinger were appointed resident physicians and surgeons on July 1st.

The hospital ambulance now covers the Community Welfare District in Yonkers between the Bronx River Parkway and Central Avenue, Midland Avenue on the south, to the town of Greenburgh on the north. With the addition of this new territory the accident service of the hospital has been greatly increased.

The Board of Governors of the White Plains Hospital has recently announced tentative plans for the erection of what is eventually to be an entirely new hospital at an ultimate cost of \$850,000, or more. The present structure, built in 1906 would be razed with the completion of the new unit, except for the north wing which was built in two sections in 1924 and 1929, which would be retained after remodeling.

The Board's action followed the several recommendations of Charles F. Neergaard, well-known local hospital consultant, who has studied the present and future hospital needs in the White Plains area.

Ossining Hospital is contemplating additions to its present plant costing up to \$125,000. A new maternity ward, a private maternity floor and possibly a new operating room are the hospital's present needs which the proposed extension would meet. A drive to obtain funds for the new construction may be made late this fall.

A new Genito-Urinary Service has been established in Dobbs Ferry Hospital under the direction of Dr John A. Whisenant, who recently was appointed to the Medical and Surgical Staff of the Hospital. A new Cystoscopic Room has been provided with modern type equipment, and Dr Whisenant is planning to conduct special clinics under this service which will be available to the community.

Francis L. Mulvihill, formerly connected with the New Haven, Conn. Hospital has been appointed superintendent of the Ossining Hospital, to succeed Miss Anna McLaughlin. The new hospital superintendent was for 13 years assistant superintendent of the New Rochelle Hospital, leaving there in 1934 to recuperate from injuries received in an auto accident.

LORENZ J. BROSNAN, ESQ.
Counsel Medical Society of the State of New York

Physicians and Surgeons—Liability for Negligence of Another Physician

One of the leading cases on the responsibility of a physician for the acts of a substitute chosen by him was decided some years ago in one of the Southwestern states*.

The plaintiffs in the action were a Mr. and Mrs. L. The husband had engaged the services of Dr. M during the approaching confinement of his wife. A visit was made to the home of the patient between 1 and 2 A.M. by Dr. M, who at that time, promised to return when needed. After leaving the patient, however, Dr. M found that he was that day obliged to attend Court on a lawsuit and that he had certain other pressing engagements of a professional nature. Consequently at 8 A.M. the same morning he got in touch with a Dr. H who enjoyed a good reputation as a physician in the community. Dr. M informed Dr. H that he might be needed during the morning, and to be in readiness.

Within an hour the husband of the patient reported by telephone to Dr. M that he thought his wife was in need of care. The doctor thereupon told L that he was unable to come, due to important business, but that he would send another physician. The response of L was a request to send the substitute in a hurry. Dr. M without delay called Dr. H and explained the case and asked him to go right out and look after Mrs. L. He instructed Dr. H to notify him if he needed help, or if anything should go wrong in which event he promised to either respond himself or send assistance.

At 10 o'clock Dr. H arrived upon the scene and proceeded to deliver the child. No dissatisfaction was expressed by the husband to Dr. H at the time concerning the arrangement and when he visited the patient a few days after the delivery L paid Dr. H the amount of the fee which he had agreed to pay Dr. M.

The husband brought suit against Dr. M both upon an alleged breach of contract and for alleged malpractice charging that Dr. H was negligent in the care he had administered to Mrs. L and that as a result she had been injured.

Upon the trial of the case the fact situation was shown to be in substance as set forth above. There was evidence provided

by plaintiff's witnesses to establish that Dr. H had in fact been negligent, and the question reduced itself to the one of whether or not Dr. M was chargeable with the negligence of the substitute. The husband upon the trial admitted that when told of the defendant's reasons for not treating the patient, he had responded by urging haste in sending another doctor.

The trial judge refused to charge the jury that Dr. M was responsible for any negligence or want of skill on Dr. H's part, regardless of the care used by Dr. M in selecting the substitute.

The trial resulted in a judgment in favor of the defendant and the matter was carried up on appeal, and finally affirmed by the highest Court in the State. The Appellate Court interpreted the facts as indicating that L had assented to Dr. M's non-attendance upon his wife, and in ruling in favor of the defendant, quoted the applicable legal principles as follows:

It is not the law that one who contracts to furnish or pay for medical or surgical aid and attention to another is liable at all events for the mistakes or incompetency of the physician or surgeon he may employ for that purpose. There must be some neglect or carelessness or misconduct on his part in the performance of his obligations arising under such contract. If he acts in good faith and with reasonable care in the selection of the physician or surgeon and has no knowledge of the incompetency or lack of skill or want of ability on the part of the person employed, but selects one of good standing in his profession, one authorized under the laws of this state to practice medicine and surgery, he has filled the full measure of his contract, and cannot be held liable in damages for any want of skill or malpractice on the part of the physician or surgeon employed.

The Court in its opinion discussed the distinction between the master and servant situation, and the situation where the person actually negligent was an independent contractor, rather than a servant. The Court found that the case before it was one where Dr. H was not in any true sense a servant of Dr. M. The reason for the distinction, it was pointed out, was that Dr. M did not retain any right of control over the acts of Dr. H. He necessarily had to act almost exclusively on his own initiative, following his own judgment.

It is interesting to note that the decision in this case has recently been relied upon

* Moore v. Lee, 211 S.W. 214

by the courts as authority to sustain the proposition that a general practitioner is not responsible for the negligence of a specialist called into a case by him, provided the general practitioner used reasonable care in selecting the specialist *

Death following Herniotomy

A middle-aged man was referred to a general surgeon for operation with respect to a condition of hernia from which he was suffering. Examination revealed a large left femoral hernia five inches in diameter, a left inguinal hernia, and a small right inguinal hernia. The doctor under a local anesthetic, in one operation making two incisions, repaired all of the conditions which were present. His recovery from the operation was uneventful for three days when he developed a temperature and his abdomen became distended and he became nauseated. The patient died the following day four days after the operation. An autopsy was performed upon the body of the patient and the autopsy report gave as the cause of death bronchial pneumonia, chronic myocarditis, chronic nephritis, and paralytic ileus.

An action was brought against the surgeon charging him with having negligently treated the patient and causing his death. The specific charge of negligence that was made was that the defendant should never have operated upon the patient since he was a chronic sufferer from heart and kidney diseases. The case came on for trial as a non-jury case and the plaintiff tried to sustain the case by the testimony of the physician who performed the autopsy and found a degree of myocarditis and nephritis. However, on cross examination the said doctor testified that there was nothing about the condition which he found in the autopsy that contraindicated the procedure carried out by the defendant. At the conclusion of the testimony, the Court decided the case in favor of the defendant thereby finding that the charges of malpractice were not well founded.

* Floyd v. Mitchie, 11 S.W. (2d) 657

Claimed Improper Examination

A woman 38 years of age consulted a general practitioner complaining of profuse menstruation. He examined her and made a diagnosis of submucous fibroid of the uterus and advised an operation. She told the doctor that she would think over the question of undergoing an operation and left.

She returned about two weeks later still complaining of bleeding. He undertook to examine her again at that time and upon introducing a bivalve speculum vaginally he found that blood was oozing from the cervix. He sponged the cervix and vagina with sterile cotton and completed the examination. He again advised operation. He did not apply any packing but sent her home, telling her that if the bleeding got worse to get in touch with him. He never saw her subsequent to that time.

Thereafter a malpractice action was instituted against the doctor by the patient in which the charge was made that instrumentation by the doctor had caused the plaintiff to bleed and that he had improperly allowed the plaintiff to leave his office while she was in the course of a severe hemorrhage.

Upon the trial of the action before a court and jury it appeared that a short time after she left the doctor's office she did undergo a severe hemorrhage and that she was taken to a hospital where an operation was performed upon her.

The plaintiff produced an expert who testified that he had recently examined the plaintiff and found her to be suffering from anemia which he attributed to shock, loss of blood, and operative procedure, which he claimed she went through due to the negligence of the defendant.

It was the contention of the defendant that the operation which the plaintiff actually underwent was precisely the same operation which he recommended and that her convalescence from the said operation was perfectly normal.

The issues of the case were submitted to the jury and a verdict was rendered in favor of the defendant doctor, thereby exonerating him of all charges of malpractice.

A WORD TO GRUMBLERS

Doctors who think their medical society dues are high are told by the New York *Medical Week* to cast a glance at the dues of \$20 in the County Lawyers Association, of \$75 in the Bar Association, of \$30 in the Plumbers Union (with \$200 initiation fee), and of \$64 in the Electrical Workers (with \$100 initiation). Instead of being high,

"the County Society dues are low—too low, in fact, to sustain the ever-expanding duties which organized medicine must assume. Many spheres of influence are closed to the profession because its official organizations have not the funds for active participation in important movements."

Across the Desk

Chasing the Hookworm Around the World

IF THE SWARMING MILLIONS of the Far East could have looked across the globe on May 31, 1889, they might have seen a sixteen-year-old boy leaping, dodging, swimming from one piece of wreckage to another as he rode the death-dealing crest of the great Johnstown flood. Hundreds were being killed on every side, including his own father and mother, but by almost super-human agility, good luck, and perhaps a watchful providence, he came through unharmed.

The boy was Victor Heiser, and in the years between that date and this he has played a leading part in the tremendous health movements that aim to eradicate hookworm, leprosy, cholera, smallpox, beriberi, plague, malaria, and other scourges of Asia and the island paradises of the eastern seas. It is not too much to say that many a little brown or yellow man enjoys life and health today because that nimble boy made the jumps from roof to roof as houses, barns, freight cars, trees, animals, and people boiled and swirled down the Cone-maugh Valley forty-seven years ago.

The story of his fight with the great plagues is now told in the most entertaining style imaginable in "An American Doctor's Odyssey" (W W Norton & Co., New York). The classic Odyssey of Ulysses seems tiny in comparison. Dr Heiser has circled the globe sixteen times in his health campaigns, and has made surveys and started or proposed health programs in forty countries. In not a few the work he helped to found is going on vigorously, and it would seem inevitable that success in one country must stimulate neighboring lands to emulation. His earlier work was in the Philippines, under the U S Public Health Service. Then in 1914 he joined the Rockefeller Foundation and for twenty years traversed the world, mainly in the Orient, starting efforts everywhere to stamp out the diseases that are crippling and wasting the strength of more than half the human race.

It would be impossible, in this brief consideration, to do any sort of justice to the more serious scientific side of Dr Heiser's volume, and the reader must be referred to

the book itself, which should be, not only in the library of every medical society, but in the public library of every city and town that aims to keep informed on what is going on in the world.

The Miracle of the Philippines

Every American, for example, should know what this country has done for the health of the Filipinos, especially at a time when we are casting them adrift to rely on their own resources. In 1903, when Dr Heiser went to the Philippines, he says, "across the street from my office was smallpox, to the right was plague, and to the left cholera." The morgue was piled high with bodies of cholera victims. Smallpox slaughtered 40,000 unvaccinated every year. Tuberculosis took 50,000, beriberi its tens of thousands. Half the babies never saw their first birthday. Ten thousand lepers wandered sadly among the well. The insane were chained like dogs beneath the dwellings. Imitation quinine pills were sold at fabulous prices. Water and food supplies were polluted and poisonous.

Turning over a couple of hundred pages of the book and eleven years of the doctor's life, we come to a refreshingly different picture. It is 1914, and he is ending his work there. "I believed," he says, "that my work in the Philippine Islands had been accomplished. The great pestilences had been brought under control, and the archipelago had become a healthful place for the white man to live in. The Filipinos, who had been a nation of invalids, were well advanced in convalescence."

A Costly Lesson

The vast story of the unrelenting labors behind this achievement could never be put on paper. In the course of a few years the health forces in the islands performed 12,000,000 vaccinations, and not only were there practically no cases of smallpox among the properly vaccinated, but "no one died as the result of vaccination, and not one arm or leg was lost." This was unprecedented, even in Germany, says Dr Heiser, and he explains "I had conceived the notion that if the scarification were not dressed, but allowed to dry, tetanus germs would be less

likely to gain a foothold. Much to our gratification, it turned out that, in trying to avoid tetanus, we avoided nearly all infection."

But it seems that the Filipinos had to learn their lesson. Four years after Dr. Heiser had left, smallpox suddenly flared up in 1918 in a great conflagration, 50,000 died of it that year, and a total of nearly 100,000 in 1918-20. General Leonard Wood, then Governor, recalled Dr. Heiser, and a probe of vaccination reports uncovered enormous falsifications, paid for in human lives. It was a costly lesson, and it is to be hoped that no repetition will be necessary.

Why the Hookworm?

Most of Dr. Heiser's work, however, has been done under the Rockefeller Foundation, and has been directed against the hookworm. He has pursued this satanic wiggler for twenty years, chasing it hither and yon around the world and starting machinery in motion that would seem likely to spell its doom. How the Foundation came to pick on this particular parasite is itself an interesting story. When the elder Rockefeller decided to turn some of his millions to the aid of the world's health, he stipulated that the fight should be waged on some widespread disease that was one hundred per cent curable, and "of which the cause can be clearly seen." That was a sticker, till his advisers thought of hookworm. "We have your disease," they said, "it is hookworm. It affects millions. We know all about it. It can be definitely cured, it is preventible, and the worm can be seen."

That is why the Foundation is tracking this pest without mercy or let-up. It is also battling many other diseases, of course, as we all know, but the hookworm is its pet aversion. Dr. Heiser's book is a liberal education on this tiny imp. We may think we know something here about it, but the entire Orient has been made hookworm-conscious with lectures, movies, public demonstrations, and voluminous propaganda. The doctor mentions with special pride an essay by a native school-girl, on some far-off Pacific isle, entitled "Parasites Lost and Parasites Regained."

One Notable Victory

It is impossible here to follow the doctor along his far-flung battle line—perhaps the

clearest way to present his war is to picture one engagement, in the Fiji Islands. Large numbers of Tamils are imported into Fiji to work on the sugar plantations, and when Dr. Heiser first saw them in 1916 they lived in miserable houses and filthy villages and seemed to have no desire for anything better. No Tamil ever smiled. The women were too anemic for childbearing and an air of misery hung over them all. In 1934 he saw them again—they were like a new creation. "They had been miraculously transformed," he says, "from a dejected, downcast, docile, uninterested people, who could not even play, into one which was healthy, alert, sport-loving, and mentally so progressive that they were agitating for schools and the vote. They owned fine fat cattle and rich lands, and had, on their own initiative, built a superior type of house, each with its neat latrine. This regeneration had been accomplished by mass-treatment for hookworm. Nothing like it has ever happened in history. At last the Tamil smiles."

The difficulties of educating brown, black, and yellow natives when you cannot speak their languages are obvious. Dr. S. M. Lambert, a fellow-worker of Dr. Heiser, went at it by learning pidgin English, the common speech of the Far East. Holding in his hand a little bottle of hookworms, he would say

"You altogedda boy. You listen good 'long dis story. One big fella sick he stop 'long bell' b'long altogedda boy. Name b'long dis sick him be hookworm. You look 'long dis bottle. Gottem plenty small snake fella he stop. Dis fella he stop 'long in bell' b'long boy. Tooth he gottem. He sabe kai kai bell b'long boy. He sabe kai kai blood. Boy him be lose him blood. He weak fella too much. Him be sick too much. Close up he die."

The Boy of Johnstown on His Way

Every kind of vehicle known on land or water has carried the doctor on his globe-girdling rounds. Rickshaws, litters, sedan chairs, wheelbarrows, gondolas, sampans, dahabeahs, proas, liners, battleships and scores of other conveyances have done duty. Four times he has missed, for one reason or another, vehicles or places where he would have met certain death.

The agility of the boy of the Johnstown

flood has sometimes stood him in good stead. Once he reached Shanghai on his way home on the very day four boats were to sail. If he could catch one, he would save a week. As he left his steamer, he saw a shiny black touring car bowling toward him. He planted himself squarely in the roadway and waved his arms like a semaphore. The Chinese driver halted and the woman alone in the car began to scream.

"Shut up!" he commanded, and she promptly obeyed. "Put my baggage in the car!" he ordered his porter. The lady objected but he paid her no attention. "Drive to the English Bund!" he shouted. Off they went, faster and faster, driving through traffic lights as he urged the chauffeur on. He found his steamer gone.

"Drive to the Chinese Bund!" he commanded, and away they flew. The steamer was just casting off. "Throw my baggage

aboard!" he shouted to a coolie, and followed it with a flying jump to the deck. The dinner gong was sounding, so he entered the dining saloon, found a place laid for one, and sat down. Soon the Captain, a bluff, red-faced Britisher, came in.

"What are you doing here?" he demanded.

"I'm one of your passengers."

"We don't carry passengers."

"Where are you going?"

"You'll have to get off!"

"I can't get off!"

Et cetera, et cetera, until, it is needless to say, the two became the best of friends and the doctor told the captain how to make his way into the port of Tientsin in a dense fog.

If the rest of the Rockefeller crusaders are anything like this Johnstown boy, the hookworm's outlook seems practically hopeless.

Books

Books for review should be sent directly to the Book Review Department at 1313 Bedford Avenue, Brooklyn, N. Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

ORDERING BOOKS

As a service exclusive to our readers, books published in this country may be ordered through the Business and Editorial Offices of the Journal (33 W. 42nd St. N. Y. C.) postage prepaid. Order must be accompanied by remittance covering published price.

RECEIVED

The Operations of Surgery By R. P. Rowlands, F.R.C.S. & Philip Turner, F.R.C.S. Eighth edition, volume 1. Quarto of 1045 pages, illustrated. Baltimore: William Wood & Company, 1936. Cloth, \$10.00.

Orthopaedic Surgery By Walter Mercer, M.B. Second edition. Octavo of 906 pages, illustrated. Baltimore, William Wood & Company, 1936. Cloth, \$10.00.

Synopsis of Diseases of the Heart and Arteries By George R. Herrmann, M.D. Duodecimo of 344 pages, illustrated. St. Louis, C. V. Mosby Company, 1936. Cloth, \$4.00.

Psychology of Sex A Manual for Students. By Havelock Ellis. Octavo of 377 pages. New York, Emerson Books, Inc. 1935. Cloth, \$3.00.

The Relief of Pain A Handbook of Modern Analgesia. By Harold Balme, M.D. Octavo of 392 pages. Philadelphia: P. Blakiston's Son & Company, 1936. Cloth, \$4.00.

The Oxford Medicine By Various Authors. Edited by Henry A. Christian, M.D. Volume 7. Psychiatry for Practitioners. Quarto of 634 pages. New York: Oxford University Press, 1936. Cloth, \$10.00.

Food, Fitness and Figure By Jacob Buckstein, M.D. Introduction by Harlow Brooks, M.D. Octavo of 252 pages. New York: Emerson Books, Inc. 1936. Cloth, \$2.00.

Heart Disease and Tuberculosis Efforts Including Methods of Diaphragmatic and Costal Respiration to Lessen Their Prevalence By S. Adolphus Knopf, M.D. Octavo of 108 pages, illustrated. Columbia County, New York: The Livingston Press, 1936. Cloth, \$1.25.

Amino Acid and Ammonia Metabolism in Liver Diseases By Esben Kirk. Octavo of 147 pages. Copenhagen: Levin & Munksgaard, Publishers, 1936. Paper, Danish Kroner 10.

Endocrinology in Modern Practice By William Wolf, M.D. Octavo of 1018 pages, illustrated. Philadelphia: W. B. Saunders Company, 1936. Cloth, \$10.00.

Theory and Practice of Psychiatry By William S. Sadler, M.D. Quarto of 1231 pages. St. Louis: The C. V. Mosby Company, 1936. Cloth, \$10.00.

A Manual of Practical Obstetrics By O'Donel Browne, M.B. Octavo of 363 pages, illustrated. Baltimore, William Wood and Company, 1936. Cloth, \$6.50.

Toxicology or the Effects of Poisons By Frank P. Underhill, Ph.D. Thoroughly revised by Theodore Koppányi, Ph.D. Third edition. Octavo of 325 pages. Philadelphia: P. Blakiston's Son & Co., 1936. Cloth, \$2.50.

REVIEWS

Essentials of Psychopathology By George W Henry Octavo of 312 pages Baltimore, William Wood & Company, 1935 Cloth, \$4 00

This book discusses the essential underlying psychology of various mental reactions. It refers to pre-natal influences as well as those acting during the life of the individual and attempts to correlate them with the symptoms the patient may exhibit, a procedure which it is felt leads ultimately to a better understanding of the person who is ill. The latter is the center of the situation and the entire situation must be studied. By citing examples that have come within his experience, the author points the way to the searching student who wishes to discover the relation of symptoms to experiences and thereby evolve perhaps some applicable therapy. It should be helpful to the student as well as the psychiatrist.

A E SOPER

Infant Nutrition A Textbook of Infant Feeding for Students and Practitioners of Medicine By Williams McKim Marriott, M D Second edition Octavo of 431 pages, illustrated St Louis, The C V Mosby Company, 1935 Cloth, \$4 50

Students and practitioners of medicine who are concerned with the nutrition of infants and children will welcome the second edition of Dr Marriott's concise and complete contribution. As in the previous edition the fundamental principles of nutrition are stressed rather than empiric outlines and methods of procedure.

The various nutritional disorders are discussed from their etiologic point of view and receive full consideration. Numerous changes have been made in order to bring the subject up to date but the general outline is the same.

LEWIS A KOCH

The Parathyroids in Health and in Disease. By David H Shelling M D Octavo of 335 pages, illustrated St Louis, The C V Mosby Company, 1935 Cloth, \$5 00

This is a thorough, truly scientific and yet eminently practical monograph on the function and diseases of the parathyroid glands. The author combines careful studies of the American and foreign literature with his own rich experience into an exhaustive survey of the subject.

Many writers of monographs, wishing to be thorough and open minded, have merely enumerated controversial opinions, to the bewilderment of the reader who is but seldom competent to choose between the disagreeing authorities. Dr Shelling has avoided such pitfalls and after marshaling his evidence takes a definite stand concern-

ing most of the moot questions. His analysis of phosphorus metabolism in parathyroid disease is particularly illuminating, especially from a practical viewpoint.

A study of this authoritative and well written book is gratifying both to the student of endocrinology and the general practicing physician.

M A GOLDZIEHER

The Diagnosis and Treatment of Pulmonary Tuberculosis A Handbook for Practitioners A Text-Book for Students, Nurses and Social Workers By John B Hawes, 2d M D & Moses J Stone, M D Octavo of 215 pages, illustrated Philadelphia, Lea & Febiger 1936 Cloth, \$2 75

The authors attempted to produce a brief and concise text book on Tuberculosis—one they hoped that would merit the description "small but authoritative." It is surprising how much solid, valuable, up to date knowledge has been compressed in the two hundred pages of this octavo volume. History taking, symptomatology, diagnosis, both physical and with laboratory aid, and treatment are stripped to all their essentials. Ideas formerly held on the subject of tuberculosis and the treatment, on climate, on heredity and on modes of infection, which have undergone change in the past generation have been brought to the present. The use of the laboratories including X-ray and pathological, with Sputum (Gaffky scale), sedimentation tests and vaccine for preventative purposes has not been overlooked. Tuberculosis in the aged as well as in children is included. Compression therapy of the lungs with indications for the several methods is well and sufficiently described, as are such accessory aids as heliotherapy, occupational therapy, diet, stressing vitamins, and the uses and indications for drugs.

The practitioner will find this book—easily read, filled with much material, obtainable at a rapid glance—of great value in his work.

THOMAS A MCGOLDRICK

The Successful Examiner By Dr Albert Seaton Duodecimo of 90 pages Indianapolis, The Rough Notes Publishing Company, Inc 1935 Cloth, \$1 00

The subject of life insurance examinations and insurance medicine as practiced today, showing the real difference between clinical medicine and insurance medicine is covered by this publication.

It contains a useful table of weights and occupational hazards tables with a list of physical impairments and underwriting practices regarding same.

The book should be useful to the examiner for informing him regarding some of the fundamentals of life insurance practices

G HOLBROOK BARBER

Radium Treatment of Skin Diseases, New Growths, Diseases of the Eyes, and Tonsils By Frances H Williams, M D Duodecimo of 118 pages, illustrated Boston, The Stratford Company 1935 Cloth, \$2.00

This small volume gives the methods of application of radium successfully used by the author over a period of thirty years. Many novel instruments devised by him are described, as well as methods of measurement taking into consideration the thickness of soft parts to be penetrated.

The author emphasizes the safety of radium both to the patient and the operator when properly used.

Part I includes a brief reference to the nature and properties of radium, the author's early studies of beta and gamma rays, measurements of radiations in air and in vacuum, and a chapter on radium in diseases of the skin and new growths.

Part II contains a description of instruments and method of treatment of diseases of the eyelids, opacities of the cornea, cataract, and other diseases of the eyes, with illustrative cases.

Part III considers the tonsils as a source of infection, prevalence of infected tonsils, other forms of treatment, instruments, arthritis, lymphoid tissue in the pharynx, and lingual tonsils, with illustrative cases.

A. L. L. BELL

The Next Hundred Years. The Unfinished Business of Science. By C C Furnas. Octavo of 434 pages. Baltimore, The Williams & Wilkins Company 1936 Cloth, \$3.00

The author made an extended visit to the Century of Progress and left it, disappointed at the meagre accomplishments.

Mr Furnas is associate professor of chemical engineering at Yale University and indicates by means of thirty-one chapters the inadequacy of our civilization. Attention is drawn to the non-utilization of scientific discovery and the almost hopeless stupidity and incompetency of society. The author begins with a discussion of the basic facts of genetics, and progresses to the unanswerable riddle—life, and then to a consideration of death.

Part two is devoted to chemistry, part three to physics, part four to engineering, part five to what is termed "The Social Consequences." The latter embraces a discussion of unemployment, of leisure without lethargy, the effects of a paralyzing demagoguery, and finally indicates what, in

the opinion of the author, is an intelligent populace, and the unsolved problems.

There is much statistical information, a great portion of which is entertainingly portrayed. Some of the problems raised are insufficiently discussed. The pattern of the book is uneven but interesting. The value is in its provocativeness for reflection on the inadequacy of society to improve itself by a fuller employment of scientific discovery.

CHARLES GORDON HEYD

High Blood Pressure and Its Common Sequelae By Hugh O Cunewardene, M B Octavo of 172 pages, illustrated. Baltimore, William Wood & Company, 1935 Cloth, \$3.00

This volume is apparently based on the observations of a limited number of cases of hypertension which have been under the care of the author and his colleagues. The material it contains is familiar to all students of the subject and some of the evidence which has been presented by others does not appear to have been critically evaluated. It is very doubtful if the book adds anything to the knowledge of this very difficult subject.

J HAMILTON CRAWFORD

Localized Rarefying Conditions of Bone as Exemplified by Legg-Perthes' Disease, Osgood-Schlatter's Disease, Kummell's Disease and Related Conditions By E S J King M D Octavo of 400 pages, illustrated. Baltimore, William Wood & Company, 1935 Cloth, \$7.50

This is a very complete monograph of a related group of rarefying diseases of bone as exemplified by Legg-Perthes' Disease, Köhler's Disease, Kienbock's Disease, etc.

The author covers thoroughly all the bones involved in this incompletely understood pathological condition. He discusses the various theories as to their cause, pathology and treatment. The value of the book is enhanced by the complete bibliography at the end of each chapter.

Every orthopaedic surgeon and all physicians interested in bone diseases should have a copy of this valuable addition to orthopaedic literature.

JOSEPH B L'EPISCOPO

A Practical Handbook of Midwifery and Gynaecology for Students and Practitioners By W F T Haultain, F.R.C.S. and Clifford Kennedy, F.R.C.S. Second edition. Octavo of 356 pages, illustrated. Baltimore, William Wood & Company, 1935 Cloth, \$5.25

As the title implies, this book is written primarily for students and practitioners who wish to refresh their memories on obstetrics and gynecology.

The material is arranged in a different

manner than in most text books, the discussion being in numerical order. The sentences are terse, clear, and very didactic. A student should find it easy to get an excellent idea of the subject from this volume, and the general practitioner will welcome a reference book in which the ordinary teaching, common procedures, complications and their treatment, are so plainly and forcefully set forth.

In this second edition, much of the subject matter has been rewritten and brought up to date, making it a small but excellent reference book.

WILLIAM S SMITH

Recent Advances in Cardiology. By Terrence East, M.A., & Curtis Bain, M.C. Third edition. Octavo of 350 pages, illustrated. Philadelphia, P. Blakiston's Son & Co. 1936. Cloth, \$5.00.

This book has been entirely rewritten and fully maintains the high standard of previous editions. The subject has been brought fully up to date and is presented in a clear manner. Not only has the literature been reviewed but a conservative critical analysis of recent work is given, which adds greatly to the value of the book. The review includes the advances in both clinical and experimental fields of the heart and peripheral circulation. Almost a small text on cardiology and peripheral vascular disease, it is invaluable as a supplement to the standard textbook and should be in possession of all those who desire to be familiar with the latest concepts in cardiovascular disease.

J HAMILTON CRAWFORD

Surgery Queen of the Arts and Other Papers and Addresses. By William D. Haggard, M.D. Octavo of 389 pages, illustrated. Philadelphia, W. B. Saunders Company, 1935. Cloth, \$5.50.

Dr. William David Haggard, a son of William David Sr., born in Nashville, Tennessee, rose to be one of the outstanding American surgeons. He is more than a surgeon, he is an investigator of clinical medicine, deeply interested in his patient as a human being.

Dr. Haggard has been President of the American Medical Association, the American College of Surgeons, the Inter-State Postgraduate Medical Association of North America, the Southern Surgical Association, and the Tennessee Medical Association. Due to the requests of friends, patients, and colleagues, he has gathered together about 33 addresses given by him during the past few years. These include a score or more of scientific contributions dealing with goitre, gastric ulcer, surgery of the gall bladder, appendicitis, intestinal obstruction, tumors of the kidney, breast

tumors, and so forth. The first address presented before the clinical congress of the American College of Surgeons in 1933, and entitled, "Surgery—The Queen of the Arts," should be read by every medical graduate and by most lay citizens.

The reviewer found it to his advantage and pleasure to read the book from cover to cover. The use of the English language by Dr. Haggard makes the book worthwhile, even though one does not agree in every detail with its text. There is a foreword by Dr. William J. Mayo, in which Dr. Mayo says, "Dr. Haggard, so to speak, takes the reader by the hand and leads him along the narrow pathways of patient scientific research onto the broad highway of achievement of the medical profession of today." This book should be on the shelf of every American physician.

MERRILL N FOOTE

Dental Infection and Systemic Disease. By Russell L. Haden, M.D. Second edition. Octavo of 163 pages, illustrated. Philadelphia, Lea & Febiger. 1936. Cloth, \$2.50.

This volume, profusely illustrated, is a most valuable contribution to Medicine and Dentistry. Its foreword is written by Dr. Edward C. Rosenow, which is significant.

Dr. Haden has compiled a large number of cases of dental infection associated with systemic disease. For the student interested in the bacteriology of dental infection much help is derived by his treatise on mediums and technique. The author's experimental observations by the use of rabbits which had been injected with the cultures from patients, would indicate a most definite relationship between non-vital teeth and systemic diseases.

The book should commend itself to every dentist and physician.

THEODORE O PETERSON

Post Mortems and Morbid Anatomy. By Theodore Shennan, M.D. Third edition. Octavo of 716 pages, illustrated. Baltimore, William Wood & Company, 1935. Cloth, \$9.00.

The book describes in detail the technique of post mortem examinations and the pathological appearance of various organs. The work is in its third edition and much of the text has been rewritten and the entire book brought up to date. It is profusely illustrated with diagrams and photographs. The descriptions are clear and make interesting reading. The morbid anatomy and post mortem technique in various forms of poisoning is well presented. There is also a chapter dealing with the manner of preserving and fixing tissues and organs, section cutting and staining of same. It is a very instructive book.

EDWARD H NIDISH

How Much Sun Does the Infant Really Get ?

Not very much: (1) When the baby is bundled to protect against weather or (2) when shaded to protect against glare or (3) when the sun does not shine for days at a time. Oleum Percomorphum offers protection against rickets 365¼ days in the year, in measurable potency and in controllable dosage Use the sun, too.

Oleum Percomorphum Price Substantially Reduced, Sept. 1, 1936!

We are hopeful that by the medical profession's continued whole hearted acceptance of Oleum Percomorphum, liquid and capsules (also Mead's Cod Liver Oil Fortified With Percomorph Liver Oil), it will be possible for us to make the patient's "vitamin nickel" stretch still further. Mead Johnson & Company, Evansville, Indiana, U S A., does not advertise to the public.

Treatise of 36 Years Close Work With Physicians in Addict Cases

— sent on request from

CHARLES B. TOWNS HOSPITAL

This defines clearly our work with and for the physician — outlines it step by step from the time physician writes us about his alcoholic or drug patient. It shows what specific attentions, what needed emergency methods, are ready at the physician's command, for these mentally baffling cases. Methods—from detoxinizing to mental reconstruction—to returning an individual who cooperates with a will!

For your reference library — detailing the many means—the direction, equipment, environment at physician's disposal

HIGH
CLASS

PRIVATE
SANITARIUM

recognized for 50
years by the medical
profession

Restricted to a limited number of nervous and mental cases—not violent, dangerous, noisy, or otherwise objectionable—with special facilities for the care of aged and chronic cases

Environment and administration are such as affords the most beneficial atmosphere. Contact with others is controlled through caring for the patients in suites (practically all with private baths). A fully qualified medical and nursing staff, physiotherapy, hydrotherapy, massage, and occupational therapy in addition to attractive and modern buildings make "Falkirk in the Ramapos" one of America's most complete sanitariums.

Convenience and accessibility in nearby accommodations and transportation for guests makes the location ideal. The sanitarium and its program of treatment are so arranged that patients have greater comfort and service than found elsewhere.

Attractive Reception Room Furniture

Modern metal furniture—as produced by DoeHLer—is excellent for reception rooms and has distinct advantages from an economic viewpoint in addition to its charm and beauty.

Clean, flowing lines combine with utmost durability and long life to satisfy the needs of the Doctor whose reception room must be in perfect taste without constant expense for upkeep.

Now that modern metal furniture has taken its place in the decorative scheme, its use in reception rooms and offices demonstrates a forward-looking attitude and the readiness to adopt new ideas when their worth is established.

Members of the Medical Society of New York State are invited to call and will be allowed the usual professional discounts on furniture for their professional or residential requirements.

DoeHLer, as you undoubtedly know, manufactures a complete line of metal furniture and equipment for hospital private and staff rooms, wards, nurses' stations, operating rooms, etc.

Select Schools

IN EDUCATIONAL AND CULTURAL ADVANTAGES

take that mind and mould it to its highest and best capabilities. The physician, too, as the family's guide, counselor and friend, may be able to do a lasting service by timely and wise advice on the right school.

The physician who is consulted about a school for this or that boy may find the answer to the question in the military academy. The special qualities cultivated at these institutions are often precisely what the young man needs. Discipline, for instance, is not merely a fine thing for any young fellow, but is specially needed by those who have not had the right amount under their own parental roof. Perhaps in our grandfathers' day the boys had too much, but the opposite is more true now, and the military school with its rigid rules, is what many boys need to build character. Along with discipline too the young man is taught self-control, something that will make him a better man as long as he lives.

And what is more, he is compelled by the very nature of his associations to learn to cooperate with others a lesson of priceless value and his daily program with its strict time-schedule, its rapid drill, its instant obedience to the word of command fills his whole being with habits of promptness and punctuality that bring him home a new chap who surprises and charms everybody. He has a fine upstanding carriage, also, in sharp contrast to the rather lax not to say slouchy or slipshod, youngster of a few months back. In short, a study of the boy's needs and of the advantages to be had at the military academy may suggest a solution that will be the upward turn in the young man's pathway of life.

Schools to Fit Every Need

A striking advantage of the private school is that the authorities study each boy and girl and shape their work and training to make good what is needed. One child needs health-care, exercise, air, sunshine, one has never learned how to study, and seems backward because of previous improper school training, another has fallen into bad company in the public schools and needs the right moral influences. All these points are carefully studied and fully met with the skill and patience that come from years of successful work in educating the whole child—physically, mentally, morally.

And what is more, the private schools have special courses of study that fit the student for particular lines of life work, where the public schools have no such provision. Perhaps the girl wishes an advanced course in finance and business management, in art, music, social training, social service, or library work. Such courses are to be had in the private schools. Or she can study medical and dental nursing or prepare to be a medical assistant, learning the proper technique, terminology, and procedures. The boy can learn mechanical and electrical engineering, chemistry, aviation, and almost anything that suits his ambition, in special schools. Any parent who has the future success of his boy or girl at heart will do well to sound out the needs and desires of the young mind, and study the lists of schools which stand well prepared to

Travel and Resorts

The Eighth Wonder of the World

Clippity-clop, clippity-clop—the rhythm of the horse's hoofs breaks a silence that is truly golden, and as he slows down for a slight grade it becomes a soft beat of clop—clop—clop—clop. Aside from this and a pleasant accompaniment of birds joining in with flute and piccolo, and a steady strumming of crickets, distracting sounds have almost ceased to exist.

The effect is so impressing that you begin to converse in low tones as if in fear of breaking the spell of an unbelievable fairyland. It is almost difficult to convince yourself that all this is real and not just a dream—and you begin to wonder if it is true that just a short forty hours ago you were a part of that din and clatter of a great metropolis.

What a soothing relief to be away from the stench of gasoline fumes, the squealing of brakes, and the nerve-wracking hairbreadth escapes of madly dashing automobiles. A tension that has been unconsciously acquired in your work-a-day life, immediately begins to let down as you become absorbed in the gentle sway of a vehicle of by-gone days.

You begin to breathe again—in great big draughts as if you would never get enough of an air as dustless as mid-ocean. The fragrance of cedar and the delicate perfume of blooming plant-life sweeten the air, and you begin to contrast it with cabbage and laundry tainted hallways, the gas works neighborhood, the odor of perspiring humanity in subways, and the thousand and one other offensive smells that surround you in the old home town.

You feel that you are being reborn—as if the Great Healer had washed away more than your sins, washed away the burdens of care, worries, and all the things that are depressing and discouraging.

You live again—forgetting that you are a doctor, one who must watch the suffering of others, feel the pain they must endure and the hopelessness when death is inevitable in a creature you have struggled to save.

If you have been to Bermuda—you know that all thus far is not a Utopian vision. You will recall the pleasantness of the cruise down, going ashore at St. George in a tender, or disembarking at the quay in Hamilton Harbour

The picture of bicycles, like a swarm of sea gulls, sweeping down to greet the visitors coming off ship is again kindled in your mind. You may remember that in the basket of one a dog was being carried, or perhaps you saw the little colored boy pedaling away with a younger sister sitting contentedly in the

basket smiling as only colored folks can.

If your visit was brief, you probably scurried to the "lilliputian" railway station for quick transportation to the caves, the Devil's Hole, and Aquarium or for a swim in sky-blue waters.

But if the stay was not limited to a few hours, your first step was probably to register at the St. George Hotel, the Castle Harbour, Belmont Manor, Sherwood Manor, Imperial, Inverurie, Elbow Beach, Langton, Hamilton, Bermudiana Princess, or the Coral Island Club. Or perhaps to choose one of the modest little guest houses—the Summerside, Gladyn, Royal Prince Victoria Lodge Argyle, American House Westmeath, Glencoe Snow Plant Inn or the Beau Sejour.

In any case you found your selected hostelry, a delightful place of hospitality and friendliness and a convenient point from which to begin exploring the islands.

If you arrived well-informed, your first experience was a carriage ride along the north shore road and around Harrington Sound visiting the caves, the Aquarium, and the Devil's Hole. Your next venture was probably a trip in the glass-bottomed boats, or a sail or a spin around the harbor in a dashing speedboat. You played golf on one of the finest courses in the world, and spent some time on horseback or cycling. You took a dip in the balmiest, clearest waters that you ever beheld.

And all this time that you were enjoying yourself every hour of the day, you looked ahead with some premonition of a regret that all this had to be abandoned and left behind. Only the aspect of another exhilarating time aboard ship, and the ties that bind you at home, kept you restrained from settling permanently. Only the feeling that you will return again and again resigned you to be contented to say *au revoir*.

Quinolor Lubricant

In Quinolor Lubricant, the Squibb Laboratories
are offering a new antiseptic lubricating jelly
whose field of service is especially broad It may
be used as a simple household application or for
scientific employment in the operating room It is
bacteriostatic and antiseptic, does not become ran-
cid, is non-irritating and not injurious to the most
delicate tissues Upon the gloved finger for digi-
tal examination or upon catheters, sounds, nozzles,
tubes or any similar instrument, it facilitates and
renders painless their introduction As an anti-
septic, it may be employed as a protective dressing
for superficial lesions

Quinolor Lubricant yields a clear zone of 5 to 6
millimeters when subjected to the "cup test" against
Staphylococcus aureus Its antiseptic power is
due to the inclusion of 0.025 per cent of a new
antiseptic substance, Quinolor, which is produced
by the chlorination of hydroxy-quinoline. Whether
applied to moist or dry surface, Quinolor Lubri-
cant spreads readily and smoothly and adheres
tenaciously It is soluble in water, may be removed
without the use of soap and does not stain cloth-
ing or linen

Quinolor Lubricant—Squibb Antiseptic Lubricat-
ing Jelly—is supplied in 2½ and 4½ ounce col-
lapsible tubes—Adv

SEX BEHAVIOR IN MARRIAGE by CHARLES A. CLINTON, M.D.

At last a book of sex technique that treats the subject frankly and in detail
without offending A medical authority proves that it is possible to cast
aside all pretense and false modesty and discuss the most important single factor
in human life in an intelligent instructive manner

SUBJECTS DISCUSSED

The Organs of Sex • Choosing the Proper Mate • The Wedding
Night • The Technique of the Sex Act • The Various Stages
of Sexual Union • Advantages of Various Positions • Impotence
and Frigidity • Frequency of Intercourse • Sex Taboos • Birth
Control

ALSO SUITABLE FOR THE LAYMAN

Here is sincere and discerning advice on the intimate details of conjugal behavior. The new and
startling revelations in this book will show the young married couple how to protect themselves from
the intricate results of abused emotions. Dr. Clinton has given in revealing yet dignified manner
correct instructions for the proper method of performing the sex act. A book any physician can recom-
mend wholeheartedly to those of his patients suffering from sexual maladjustment.

It is the purpose of this book to give exact instructions for marital procedure.
Dr. Clinton's long years as a physician and wide clinical experience merit your
confidence.

There will always be a difference of opinion concerning the things entitled to be included among the seven wonders of the world—but ask the person who has made a first trip to Bermuda, or the person who has made Bermuda a habit, what is the eighth wonder of this planet and it's a safe wager they'll say, "Bermuda!"

* * *

Lake Placid Traffic Heavy

The combination of the "Month of Flaming Leaves" and the Whiteface Mountain Memorial Highway is bringing motorists by the thousand into this section of the Adirondacks.

Figures released by J. Hubert Stevens, vice-chairman of the Whiteface Mountain Highway Commission show that from May 15 to September 10 of this year 54,049 people made the ascent of the mountain, and 15,589 cars were checked through the toll gateway. These figures contrast with the entire 1935 season, July 20 to November 15, people, 45,561, cars, 15,061.

On September 10, 1936, the total figures on traffic up the road during the periods that it was open in 1935 and 1936 were people, 99,610, cars, 30,650.

The heaviest single day's traffic in 1935 was on September 1, when 1,825 persons went up the mountain. The heaviest day in 1936 was on September 6, when 2,332 motorists made the ascent.

Search of local newspaper files has brought to light the fact that the first known plan for a road of any sort up Whiteface was conceived in 1898, when J. N. Stowel, then general manager of the Delaware & Hudson Corporation, was asked to prepare for R. M. Oliphant, president, plans for a cogwheel railroad up the western slope of the mountain. Mr. Stowel also proposed building a small hotel at the summit and terminal stations at the base and at the foot of Lake Placid, approximately six miles distant. Two steamers were to ply the lake taking passengers from the dock to the station at the base of the mountain, and tickets were to be sold from New York and points on the Delaware & Hudson directly to the peak of Whiteface.

The estimated cost of this plan was \$100,000. It never got beyond the "plan" stage, however, and was subsequently dropped.

Trips to Resorts Becoming Social Events

British society people have recently created a new kind of train, the 'Society Special', which promises to become as popular in its own exclusive field as the most inexpensive excursions are with factory or white collar workers. The new type of Special is said to have developed in the following manner:

So many prominent people, who know each other, leave at about the same time in the summer season for the fashionable Gleneagles in Scotland that someone suggested that they make a pleasant social event of the trip to and from the famous resort. The idea 'caught on' immediately, with the result that a group of the most prominent people in London engaged a special train for the week-end. The 'Society Special' was composed of sleeping and refreshment cars, and made the trip from London to Gleneagles during the night. The hotel management fell in with their mood and gave the party a private dining and sitting room.

During the following two days the society excursionists, most of whom are enthusiastic golfers, played on the celebrated Gleneagles courses and, on Sunday night, left for London so pleased with the 'Society Special' that they voted to make the trip an annual event.

Babies by Air

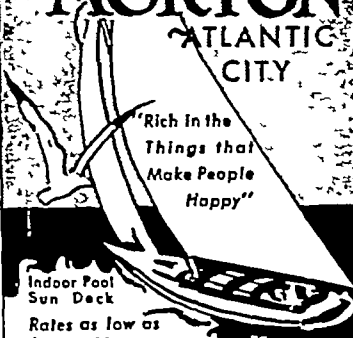

Transportation of infants by air is increasing—the latest example being the case of three months' old Martin Thomas son of Dr. and Mrs. Thomas Ferwerda of the Naval Hospital at the Navy Yard in Brooklyn.

A husky, eight-pound boy, only three months old, he was the youngest smallest child ever to fly from coast to coast without its parents according to United Air Lines officials.

Dr. Ferwerda was attached to Vancouver Barracks in Portland Ore., on May 31, when Martin arrived one month prematurely and weighing only three pounds, two ounces. He spent his first six weeks in an incubator while his parents went to Brooklyn.

Daily bulletins announced that Thomas Martin was thriving in St. Vincent's Hospital Portland on a diet of orange juice and canned milk, under the care of Miss Bee Saunders, a private nurse. In due time it was decided that

ATLANTIC CITY, N. J.

Close to the Gulf Stream, the resort boasts of a mild climate and summer goes on and on with thousands of bathers still taking advantage of the beach and surf. Visitors who took to the mountains during the warmer months are coming to the seashore for a change of scenery before returning to their homes inland for the winter season.

The Boardwalk, a year 'round attraction, is still well filled with promenaders in the afternoon and early evening. The evening band concerts on the Boardwalk in front of the municipal convention hall will continue until late next month.

The beach will be thrown open to equestrians on October 1 and one of the world's finest bridle paths, a wide flat stretch eight miles long will be available. Meanwhile main land bridle paths, particularly attractive at this time of the year, continue popular. The crisp salt air and warm sunshine make riding on the beach really enjoyable and each day will find hundreds taking advantage of this.

Open from 6 a. m. to 9 a. m., the Boardwalk bicycle lane is getting its usual large quota of cyclists each day. The 'walk, eight miles long, provides what is probably the safest bicycle lane in the country.

The fall golf tournaments are underway on the nearby courses at Northfield, Linwood, Somers Point, Brigantine and Seaview. Each club reports that the weekends bring a huge influx of golf enthusiasts.

Fishing, too, continues good and the visiting anglers are returning to the docks with huge catches. Boats at the Atlantic City Tuna Club and the Inlet Yachting Center will be making their daily trips to sea or up the back bay as long as the fish continue to bite. Tuna are still in these waters as evidenced by the fact that Daniel Stebbins, local sportsman, returned the other day with a 535 pounder caught twenty miles off here.

Hotel grilles, night clubs, ocean piers and theatres are still well patronized as the resort's banner season continues. The start of the convention season finds slightly less than 40 large three and four day gatherings scheduled for the next three months and the resort is preparing to entertain thousands of guests here for business rather than pleasure. Among the larger groups are the American Bakers Association, Annual Safety Congress and Exposition, International Association of Milk Dealers, American Gas Association, and the American Association for the Advancement of Science.

Albert H. Skean, chairman of the Atlantic City Camera Contest, with headquarters on Central Pier, announced that summer visitors

its famous resort hotels Nassau-in-the-Bahamas, lying farther south, is exotically fascinating, not only in its native life, but in the glamour and color of its resort life

These interludes ashore, however, are only a part, and only a small part of the Triangle Cruises. Most popular with the hundreds who have made these voyages are the days at sea aboard the great luxury liner, where every detail has been carefully planned for the comfort and amusement of the passenger, and there are special programs of entertainment.

Frequently according to Mr Findlay passengers find the Bermuda trip too short to fully enjoy the numerous facilities for amusement and entertainment at sea. There are deck sports, built specially wide and unobstructed, with shuffle board, horse-racing and other amusements provided under the supervision of experienced cruise managers. There are great, comfortable lounges, with complete stages and equipment for showing the latest sound pictures. An important, and popular feature, the swimming pool, provides amusement night and day, with small tables where passengers may sit and sip drinks between plunges. In the evening there are the ships' beautiful bars, and the dance floors, specially constructed at a cost of over a quarter of a

million dollars, with twin verandah cafes at either end.

But perhaps one of the best indications of the luxury of the "Queen of Bermuda", as well as her sistership the "Monarch of Bermuda", is the fact that every stateroom, even at minimum is equipped with a private bath—a feature present only on these two vessels.

Regular service to Bermuda will be maintained by the "Monarch of Bermuda", while all of the Triangle Cruises will be made aboard the "Queen". Both islands are definitely established as the two most popular resorts.

Reports filed with the Interstate Commerce Commission show that in 1935 there were 865,098 railroad stockholders. The number of railroad bondholders is not reported but is estimated at one million

Triangle Cruises Again Feature Fall Program

Bermuda and Nassau - in - the - Bahamas, friendly rival resort islands of the Atlantic, will again be the goal of a series of Triangle Cruises sailing October 27, November 5 and November 12 aboard the "Queen of Bermuda," a vessel pleasure-planned for the transportation of passengers only. Each of the new Triangle Cruises, which have annually attained greater popularity, is of seven days' duration, with a full daylight day in both Bermuda and Nassau and six days of luxurious ocean cruising

Conceived to meet a growing demand for longer voyages aboard the two great luxury liners "Queen and Monarch of Bermuda," James N. Findlay, Passenger Manager of the Furness Bermuda Line, has found the traveling and vacationing public is quick to take advantage of a cruise which combines visits to the two famous islands with the many amusement facilities of the Furness Bermuda liners

Variety is the essence of these cruises. Bermuda, most popular of pleasure islands, where the visit is made only two days after leaving New York, offers its beaches, its championship golf courses, and the gay resort life of

tions and their escorts that flavor of play which is an attraction of all continental resorts, so roulette and baccarat have their place here.

If many who come never stir out of the parks, never stray far from the sound of music there are many others who prefer sports to complete their cure. These more active visitors will cross the river to the attractive Sporting Club, set in its flower beds, looking across the Allier on one side and across the golf links to the low Auvergne hills on the other. Two courses here await them, putting greens and croquet grounds offer milder outlets, and just beyond are the numerous tennis courts. Almost weekly competitions stimulate interest in all sports, and at tea-time the tables under the big parasols become animated as a dozen languages are spoken. Fencing tournaments are held in one of the hotels of the spa, or in the Galerie Napoleon each year, regattas are to be watched on the river, fishermen idle in their boats all day, and in the spring and mid-summer two big racing seasons and a horse show draw riders and turf-lovers to these annual Vichy sporting events.

But social life, especially for the ladies often demands more than this. Thus we find tea dances on the Casino terrace, a night club under the Thermal Palace gala dinner-dances at the Carlton annual Automobile Elegance Competitions, and innumerable other attractions.

Children are now coming more and more frequently to Vichy for the cure, and there are those whose parents must have their minds at ease while taking their cure. For them the fine new children's sport field under medical attention has just been completed down in the river parks, where they may pass the entire day in perfect content, and for them costume competitions, Punch and Judy Shows, and other joys are available.

If the mind is of the type that will not leave one tranquil even during a cure, the Historic Museum of Vichy is open and the *Maison du Missionnaire* arranges illustrated lectures on aspects of colonial life.

These are the things that are always happening—and yet we have not touched on the special occasions which brighten the life of a spa, such as provincial fetes with the natives dancing in their pretty Bourbonnais costumes or the Coldstream Guards in their great hats parading through the streets with their band.

There is a tremendous amount of organization necessary to assure the smooth functioning of all these varied aspects of the life of the spa. The direction of the *Compagnie Fermiere*—which rents or "farms" the springs

from the Government under contract to improve the station constantly, the municipal authorities, the fetes committee, the *Syndicat d'Initiative* all these must cooperate if strangers coming from around the world are to find health and pleasure simultaneously in a town like Vichy.

* * *

Four Canadian Pacific Liners to Carry Coronation Passengers

The pageantry and glamor surrounding the coronation of King Edward VIII at Westminster on May 12 next will attract thousands of Canadians and Americans to England, in the Spring of 1937.

Steamship bookings are already being made by many prospective travellers. Liners sailing from Montreal and Quebec during April especially the latter part, are expected to be as well filled as any midsummer crossing.

Four Canadian Pacific sailings during the latter part of April are scheduled to carry the tourists to Great Britain in time for the Coronation and a preliminary tour of the British countryside. These are the *Duchess of York*, leaving Montreal and Quebec April 23 for Glasgow, Belfast and Liverpool, the *Empress of Australia*, leaving Quebec April 24 for Cherbourg and Southampton, the *Duchess of Atholl*

in the Western Hemisphere, a fact demonstrated by the fact though Bermuda was conceived originally by the traveling public as a wintering resort, during the past summer it enjoyed the largest number of visitors in its history. During the latter part of March and during April, Mr Findlay said, arrangements have been made to charter the *M V Georgic*, of the Cunard White Star Line, placing in service over the Easter Holidays an augmented schedule for the convenience of spring visitors to Bermuda.

Vichy, Spa of Many Aspects

The simplest psychology teaches us that a happy man is near to being a well man, and the organizers of life in any watering-resort must therefore take into account that while curing a visitor's bodily ills they must also cure any mental depression which may have resulted therefrom. And just as there must be bathing facilities of varying degrees of luxury to suit different tastes and different purses, so must there be recreation facilities to suit these same tastes and purses.

Thus a spa like Vichy has only begun its work when it has built and equipped its white

palace which proves on inspection to be the Grand Thermal Establishment, its curiously exotic temple, which turns out to be the big modern second-class Callou Baths built on the site of an old Capucine monastery, and its still newer third class baths now under construction down by the river parks. When it has installed a sufficient number of rooms for under-water massage, Vichy douches, obesity reducing, irrigations and mud packs, when it has provided the biggest meconotherapy institute in the country, and turned its attention toward swimming pools, when it has seen to it that its pump-houses are fresh and clean and its *donnouse d'eau* crisp and smiling in their blue and white uniforms, then it must turn its thoughts elsewhere and make provision for those hours when one is not being massaged or baked, when one is not just 'drinking the waters.'

First of all, since people taking a cure should normally walk for exercise, the parks must be made inviting. Vichy offers two parks, one of which is a great rectangle stretching between the principal Springs, called the Park of the Springs. It is at its best in the spring, when the long rows of majestic chestnut trees are loaded with huge pink or white blossoms. The other is the River Parks, which lie down along the river Allier, here an amazing variety of tree and floral life is to be found, and even a tiny zoological garden, with flamingoes in ponds and antelopes in enclosure.

To help keep people out in these parks, as they cannot walk all day be the sites ever so inviting, outdoor concerts are arranged for every morning and afternoon, and it is safe to say that a good proportion of those who take their three weeks cure in Vichy sit under the trees or the pergolas of the Park of the Springs and listen happily to forty-two excellent concerts. They may even come back again in the evening, to the terrace of the Grand Casino which blocks one end of the park, where the third daily open-air concert takes place.

This musical aspect of the spa is further developed inside that Casino, where the summer evenings see a succession of some of the greatest singers, musicians, and orchestra leaders of the world. Lauri Volpi and Martinelli, Sir Thomas Beecham and Karl Elmendorf, Piatigorsky and a hundred others pass before the footlights in this one summer, and alternating with this music are great artists like the regretted Argentina, or plays with their casts fresh from the Paris theatres.

But the Casino must also provide for the beautifully gowned women of two-score na-

When Called to New York for consultation or convention

You'll find the comfort, charm and privacy of a well-managed home awaiting you at THE BARCLAY, combined with

● CONVENIENT LOCATION—a step from Grand Central Station on bus and subway routes leading to hospitals and medical centers a short distance from Broadway theatres and the better men's shops

● ECONOMICAL LIVING—parlor suites with serving pantry and electric refrigeration \$10 \$12 and \$15
Single rooms \$5 \$6 and \$7 Double rooms from \$8

● DISTINCTION—patronized by discriminating people in the different professions and in business

Experiences of an American Lady

"Never in all my life had I expected to see anything as beautiful and enjoyable as Bad Nauheim!", writes Mrs Arthur Liebe, of 3433 North Frederick Avenue, Milwaukee, Wisc., about her visit to the famous heart resort in the Taunus Mountains of Germany. "And to think", she continues, "that I went there quite by accident! I have traveled a great deal in Europe, including Germany, but it had never occurred to me to visit Nauheim, thinking as I did that it just was one of the many small though attractive German watering places. However, when I developed heart trouble several months ago and my physician in Milwaukee suggested that I try the cure at Bad Nauheim, I decided to follow his advice, and I am grateful to my lucky star that I did. Nauheim is a veritable paradise, with its abundance of flowers, particularly roses, and its lovely landscaped gardens. And there is every opportunity for the guests to enjoy themselves as they like best.

"The hotel at which I stayed offered all the modern conveniences imaginable, and everyone I met treated me with the utmost friendliness, courtesy, and consideration. I certainly expect to visit Nauheim again next year to take the cure and to renew the many pleasant acquaintances.

"My niece, Mrs Richard Momsen of Rio de Janeiro, who happened to pass through on her tour of Germany, was so enchanted with the place that she promised to spend the best part of her next European sojourn here with me."

ACID RESISTANCE WITH **KALAK**

Hypertonic—Alkaline—Carbonated—Not Laxative

The years of experience with physicians who have used Kalak show that the use of a formula containing calcium, magnesium, sodium and potassium salts represents a correctly balanced solution. This is Kalak which, as such, aids in maintaining a balanced base reserve.

How Alkaline Is Kalak?

One liter of Kalak requires more than 700 cc N/10 HCl for neutralization of bases present as bicarbonates. Kalak is capable of neutralizing approximately three quarters its volume of decinormal hydrochloric acid.

GAUZE BANDAGE

Notice to the Profession:

In order to facilitate the introduction of SANITIZED GAUZE BANDAGE, the manufacturers invite physicians to request free samples, which will be furnished to the extent of the available "trial supply"

Concurrently with clinical observations now being recorded, independent tests by individual physicians are encouraged

SANITIZED GAUZE is processed in the manner of the many commercial products now vended under the protected trade-mark "Sanitized"—such as MILK BOTTLE CAPS, LAUNDRY, TEXTILES, LEATHER, HAIR, COTTON, etc.

SANITIZED GAUZE may be suggested worthy of trial, especially in suppurative cases

SANITIZED GAUZE claims (★) are founded upon the qualification of individual elements as set forth in the U S Pharmacopoeia and other authoritative references

The SANITIZED process is an unusual prophylactic contribution but not the elements thereof

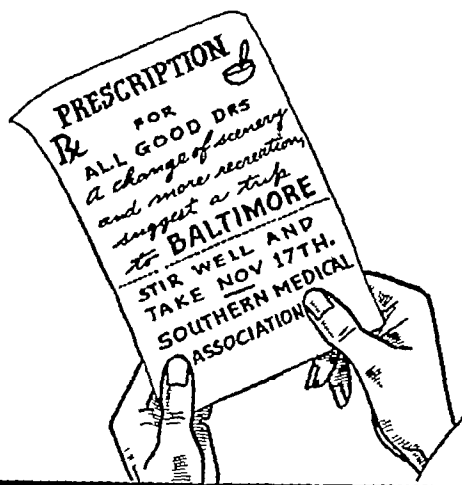

SANITIZED as an achievement is another milestone on the road now marked by PASTEURIZATION and STERILIZATION

SANITIZED GAUZE meets a definite antiseptic and sterility standard, copies of which may be secured upon request

SANITIZED LABORATORY records and research data available for review

AN OUTSTANDING MEDICAL MEETING — the Annual Meeting of the Southern Medical Association in Baltimore November 17-20 In the twelve general clinical sessions, the sixteen sections, the five independent medical societies meeting conjointly, and the scientific and technical exhibits, every phase of medicine and surgery will be covered—the last word in modern, practical, scientific medicine and surgery. Addresses and papers by distinguished clinicians not only from the South, but from all over the United States

Regardless of what any physician may be interested in, regardless of how general or how limited his interest, there will be at Baltimore a program to challenge that interest and make it worth while for him to attend.

MEMBERS OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK (white), in good standing, are most cordially invited to attend the Baltimore meeting of the Southern Medical Association as visitors with all privileges of members except voting in the business session—all scientific and social activities are available to visitors No registration fee.

An X-Ray Power Plant About the Size of Your Hat

**—YET SURPRISINGLY EFFICIENT
FOR OFFICE AND PORTABLE WORK**

WHEN both the high-voltage transformer and x-ray tube are immersed in oil and sealed within the same container, you have a unit which in bulk seems exceedingly small when compared to the amount of x-ray energy it delivers. But that's the result of *complete* oil-immersion, also the reason for its shockproof operation.

Hundreds of physicians have found this G-E Model "F" Office-Portable X-Ray Unit to be just what they had long wanted—a small unit to be set on the desk, ready for service by simply plugging in to the nearest electrical outlet when a simple radiograph or fluoroscopic examination is desired. In the management of fracture cases especially, the location of foreign bodies, or for emergency service in the patient's home, these users find it practically indispensable—a convenience both to themselves and their patients.

It's highly probable that you are skeptical of the ability of such a small x-ray unit to serve a worthwhile purpose. If so, then do as most present users of this unit did—ask us to put it through its paces—right in your own office, and without any obligations.

FREE TO DOCTORS!

Heinz Offers New Third Edition of Famous Nutritional Charts

Now you can get complete descriptive information about the nutritional values of foods—in one handy volume that's yours for the asking! Heinz book of Nutritional Charts—revised and brought up-to-date in a *third* edition—contains data covering the latest developments in vitamin and nutrition chemistry!

Packed within its 32 large-size pages is the cream of scientific research on human nutritional requirements. Outstanding bulletins, government and state bureau circulars, special review articles, and original contributions have been condensed for your convenience. Every authoritative source has been utilized to make the *new* Heinz Nutritional Charts better than ever!

At your fingertips are the latest facts about the chemical and biological properties of vitamins and minerals. Outlined in easily accessible form is reliable information on

food allergy, so-called food poisoning, food fads, alkaline and acidic effect, and the toxicological aspects of diet. Here, in effect, is a convenient source of accurate information useful in prescribing diets for children, the sick and convalescent, that would take you days to look up elsewhere!

Write for your free copy of the Heinz Nutritional Charts now! See for yourself what a wealth of valuable material this handy new edition contains. There's no obligation. Just address your request to H. J. Heinz Co., Dept. NY310, Pittsburgh, Pa.

MORE AND MORE MEDICAL MEN throughout the United States are giving their exclusive recommendation to Heinz Strained Foods for infant and other soft diet cases. Their reason—only Heinz Strained Foods bear *both* the famous "57" Seal of Quality and the Seal of Acceptance of the American Medical Association's Council on Foods.

HEINZ STRAINED FOODS

11 KINDS—1. Strained Vegetable Soup. 2. Peas. 3. Green Beans. 4. Spinach. 5. Carrots. 6. Beets. 7. Prunes. 8. Cereal. 9. Tomatoes. 10. Apricots and Apple Sauce. 11. Mixed Greens.

Thanks to you —

The NEW YORK STATE JOURNAL OF MEDICINE has again increased in size — one hundred and sixty pages of exceptional and diversified scientific articles, pointed editorials by one of the country's best medical editorialists, news gleanings from the witty pen of an internationally known journalist, and helpful advertisements of local and national business establishments

Since the change in style of the official publication of the Medical Society of the State of New York, less than three years ago, improvement in every department has been most perceptible. From forty-four text and twenty advertising pages — the JOURNAL has increased in size to one hundred and ten text and fifty advertising pages. The number of advertisers has increased from forty to one hundred and forty-three. Space used by advertisers has jumped from 818 square inches to 1,940 square inches. From the first step in preparing an issue for publication to the time it is delivered, more than one hundred persons (excluding post office employees) directly or indirectly assist in getting it to you. For this issue six tons of paper were required.

At its present size almost four hundred original scientific articles will be required in a year. During the past twelve months five hundred and forty papers were submitted, three hundred and twenty-five rejected, two hundred and fifteen published. Based on the same ratio — approximately one thousand manuscripts will have to be reviewed for the next twenty-four issues.

Impressive, to say the least. And thanks to you — the increasing attractiveness of the JOURNAL adds daily new readers and new advertisers. Patronizing our advertisers has aided materially in building up a publication that has become a leader in its field.

GARFIELD ULTRA SHORT-WAVE

6 METER, 400 WATT OUTPUT, is a combination of TUBE and SPARK GAP with most unusual characteristics

Simplicity of operation and function

Air Spaced Electrodes, mounted on Arms, conveniently concealed with other Electrodes in compartments on side of cabinet

Why the State of New York Bottles Three Different Waters at SARATOGA SPA

IN crenotherapy the desirability of a possible gradation in the amount of mineral intake is self-evident.

It is a unique asset of the saline-alkaline springs at Saratoga Spa that there is a wide variance in the percentage of their mineral constituents. Three waters are bottled for general therapeutic use, waters which take their names from the individual springs—Hathorn II, strongly saline, Coesa, mildly saline, and Geyser, alkaline-saline.

With three different waters of similar general classification at command, the physician is able to prescribe to the needs of the individual patient.

Analysis of the Three Waters

CENTRAL PARTS PER MILLION

Hypothetical Combinations	Geyser	Hathorn	Coesa
Ammonium chlorid	61.17	59.10	39.77
Lithium chlorid	27.00	64.49	42.43
Potassium chlorid	233.81	763.54	349.00
Sodium chlorid	2,511.61	8,594.64	4,930.39
Potassium bromid	32.00	160.00	16.00
Potassium iodid	1.60	4.63	2.00
Sodium sulphate	Trace	None	None
Magnesium sulphate	Trace	None	None
Sodium metaborate	Trace	Trace	Trace
Sodium nitrate	Trace	Trace	Trace
Sodium nitrite	Trace	Trace	Trace
Sodium bicarbonate	2,205.54	424.71	433.70
Calcium bicarbonate	1,677.09	3,380.84	2,545.74
Barium bicarbonate	Trace	25.65	39.03
Strontium bicarbonate	Trace	Trace	Trace
Ferrous bicarbonate	23.15	40.07	14.25
Magnesium bicarbonate	874.71	2,244.83	1,378.52
Alumina	1.59	4.93	2.70
Silica	6.60	14.40	9.60
Total	7,856.87	15,809.30	9,801.22

This means that an 8 oz. tumbler of Geyser Water for instance contains 28 grains of minerals of which 18.2 are acid-forming bicarbonates. Other mineralized waters boast when they can show 3 grains.

Look for the Seal of The State of New York on every bottle of the genuine waters of Saratoga Spa.

THERAPEUTIC NOTES

In rationalizing the results observed in thousands of cases, we can now look beyond the well known relation between inorganic ions and healing action, and consider the anomalies that result from the spatial lattice molecular structure of water, itself and of these natural electrolyte solutions, thus demonstrated to be distinct from artificial preparations.

The natural carbon dioxide in Saratoga Spa Waters acts as a stimulant to the mucous membranes, resulting in increased gastric secretion and peristaltic activity. Taken internally the waters all result in definite

diuresis and will increase the alkaline reserve of the body.

For gastrointestinal conditions, the indications are primarily those associated with under-activity, such as functional conditions of the stomach resulting from hyposecretion and hypomotility.

The waters (Coesa) are also used with great value in treating congestion of the liver and poor elimination from the gall bladder. Results in some patients with gall bladder conditions, are evidenced by the elimination of small concretations from the gall bladder of a size which may pass through the cystic and common ducts.

Interested physicians are invited to send for a professional sample package of four bottles, and medical literature. In writing please use your business stationery.

SARATOGA SPA IS OPEN THE YEAR 'ROUND FOR THE TREATMENT OF CHRONIC DISEASE

Say you saw it in the Oct. 15, 1926 issue of the N. Y. State J. M.

IRON • CALCIUM PHOSPHORUS VITAMIN D

*in this one delicious
high caloric food-drink*

DURING convalescence from illness, an operation or childbirth—or when it is advisable to increase the weight of a malnourished child—*there is one food drink which has proved itself exceptionally useful*

That food-drink is Cocomalt. Delicious and tempting, easily digested and quickly assimilated—Cocomalt not only adds easily assimilated Iron to the diet, but also richly provides Calcium, Phosphorus and Vitamin D.

An ounce of Cocomalt (which is the amount used to make one cup or glass) supplies 5 milligrams of Iron in easily assimilated form. Thus three cups of Cocomalt a day supply 15 milligrams—*which is the amount of Iron recognized as the normal daily nutritional requirement*.

Here, then, is one form in which even a capricious child or a finicky adult will take Iron willingly—and at the same time receive other important food essentials. Prepared as directed, Cocomalt adds 70% more food-energy value to a glass of milk.

Vitamin D, Calcium, Phosphorus

Cocomalt is fortified with Vitamin D under license granted by the Wisconsin Alumni Research Foundation. Each ounce of Cocomalt contains not less than 81 USP Vitamin D units.

Cocomalt also has a rich Calcium and Phosphorus content. Each cup or glass of Cocomalt in milk provides 32 gram of Calcium and 28 gram of Phosphorus. Thus Cocomalt supplies in good biological ratio three food essentials required for proper growth and development of bones and teeth: Calcium, Phosphorus and Vitamin D.

FREE TO DOCTORS: We will be glad to send a professional sample of Cocomalt to any doctor requesting it. Simply mail this coupon with your name and address.

R. B. Davis Co. Dept. 31-K, Hoboken N. J.
Please send me a trial size can of Cocomalt without charge.

WILLOUGHBY'S

The World's Largest Exclusive Camera Supply House
110 West 32nd Street New York

Just a year ago Lederle introduced—

GLOBULIN **Lederle** MODIFIED

ANTITOXINS

IT HAS BEEN A YEAR of appraisement and ever-increasing usage. The Globulin-Modified *Lederle* technique, embodying the principle of peptic digestion, is the only practical procedure which permits such a high degree of concentration of antitoxin and reduction in the amount of troublesome proteins—the cause of serum reactions.

That is why Globulin Modified Antitoxins *Lederle* represent

- a reduction in the expected incidence and severity of serum disease,
- less inconvenience to the patient,
- a greater ease of administration,
- a greater potency per cc

At one of the outstanding hospitals 250 patients treated with a Globulin Modified Antitoxin showed a serum disease rate of less than 5%—all indicating a delayed type of serum reaction.

A Safe, Tempting Form of Protein

U S P Gelatine is being prescribed more and more in the diet of the diabetic Knox Sparkling Gelatine in particular It contains no carbohydrates, coloring matter or flavoring (as in factory-flavored jells), therefore can be used generously with complete safety

Knox Gelatine can be employed to make a hundred and one flavorsome and appetizing dishes which add color and variety to the diabetic's usually monotonous menu This brightens the patient's mental state High in nutritional and caloric value, it is readily assimilated and utilized

Quite a remarkable product—made as carefully as an ampule solution For the diabetic, convalescent, tubercular, high-protein, post-operative and infant diet where higher protein content is desirable

Dinner for Two

As soon as the "mother-to-be" is aware of her condition, she is immediately committed by nature to the task of eating for two. The food she consumes from then on to the date of delivery, should be sufficient in quality, quantity, and variety, to maintain her own well-being and to supply "building material" for the one dependent upon her.

If you are the attending physician, your responsibility for what she eats, in your concern over bringing another fine baby into the world, has also started. What do you prescribe for her diet?

Shortly, she is unable to indulge in excessive exercise—and consequently you must discourage heavy, hard-to-digest foods. Her "dinner for two" must furnish vitamins and mineral salts in sufficient quantity for *two* bodies—yet be well prepared and light enough

so as not to overtax *one* set of digestive organs.

Your problem of prescribing proper food for "mothers-to-be" has become more simplified. Selection is no longer limited to raw products available or to the extent of the woman's ability to cook. Progress in commercially prepared foods has become marked no less in flavor, than they have in varieties, purity and safety. Scientific equipment has made prepared foods higher in food value for many reasons, and free from contaminating micro-organisms.

Unfortunately all food packers and producers, or their products, are not on par as to quality and efficiency—it is advisable to specify particular brands, chosen from your advertisers in the JOURNAL at all times that special diet foods are indicated when "two must live as one."

PURE TOMATO JUICE

by the Trainload

Again this year New York received the first shipment of new pack Kemp's Sun-Rayed Pure Tomato Juice. This non-separating, undiluted tomato juice of *proved* vitamin potency is one you can recommend with confidence. Available at practically all chain and independent food stores. Send for FREE copy of Steenbock Report J-36 on Feeding Tests, THE SUN-RAYED CO. (Division Kemp Bros. Packing Co.), Frankfort, Indiana.

Dull the consciousness of PHYSICAL DISCOMFORT

SLEEP in the normal healthy person provides an adequate period of physical and mental recuperation. Where normal sleep is disturbed by worry, excitement, pain or physical discomfort, hypnotics or sedatives are often indicated.

Ipral Calcium (calcium ethylisopropylbarbiturate) induces a sound, restful sleep closely resembling the normal. It is readily absorbed and rapidly eliminated. Undesirable cumulative effect may be avoided by proper regulation of the dosage. No untoward organic or systemic effects have been reported in the usual therapeutic dosage. Ipral Calcium is supplied in

2-gr tablets for use as a sedative and hypnotic.

Ipral Sodium (sodium ethylisopropylbarbiturate) is supplied in 4-gr tablets for preanesthetic medication.

When pain accompanies insomnia, Tablets Ipral Aminopyrine (2 gr Ipral, 2 33 gr Aminopyrine Squibb) provide both analgesic and sedative effects.

These preparations are available in bottles of 10, 100 and 1000 tablets. For descriptive literature address the Professional Service Department, 745 Fifth Avenue, New York City.

IPRAL Sodium

...THE TRIPLE TEST IN PRACTICE!

THE ETERNAL TRIANGLE dominates the lives of products, even as of men. In infant feeding the doctor is concerned with the three factors—*composition*, *concentration* and *cost*!

Apply the triple test in your practice. Let us now put it to Karo.

(1) **Composition** — When you prescribe Karo as the milk-modifier you are providing well-tolerated, readily digested maltose-dextrins-dextrose. The dextrins are non-fermentable, the maltose rapidly transformed to dextrose requiring no digestion, the sucrose added for flavor is digested to monosaccharides. Karo is prepared chemically superior, bacteriologically safe—non-allergic, practically free from protein, fat and ash.

(2) **Concentration** — When you consider that volume for volume, Karo Syrup furnishes *twice* as many calories as a similar sugar modifier in powdered form, you realize *how* strongly saturated Karo is in calories of maltose-dextrins-dextrose. A tablespoon of Karo Syrup yields 60 calories while a tablespoon of powdered maltose-dextrins-dextrose gives 29 calories. Karo Syrup is a concentrated milk-modifier!

(3) **Cost** — When you prescribe Karo you help the family out of the economic dilemma.

Karo Syrup contains twice as many calories as

Powdered Maltose-Dextrins-Dextrose including Karo Powdered

Karo costs $\frac{1}{5}$ of the expensive carbohydrates, slashing the high cost of infant feedings. The maltose-dextrins-dextrose of Karo are marketed as a food. The saving is 80%. The Corn Products

Refining Company charges for the constituents of Karo and nothing extra for the good name. Apply the triple test to milk-modifiers and you will find Karo desirable in composition, rich in calories, and inexpensive. Karo consists of dextrins, maltose and dextrose (with a small percentage of sucrose added for flavor).

Corn Products Consulting Service for Physicians is available for further clinical information regarding Karo. Please Address Corn Products Sales Company, Dept. NM-10 17 Battery Place, New York City.

**THE INDUCED HYPOGLYCEMIC STATE IN THE TREATMENT
OF THE PSYCHOSES**BERNARD GLUECK, M D, *Ossining*
*Medical Director, Stony Lodge***I**

The writer recently called attention to the available statistics concerning the therapeutic effects of an induced state of hypoglycemia in the treatment of schizophrenics¹. These statistical findings are the product of the collaboration of twelve European private and public hospitals employing this method.

The bulk of the Swiss clinical material and some of the Vienna material upon which these statistics are based was made accessible to the writer through a careful study of the clinical records, through personal interview with a considerable number of the recovered patients and through the actual participation, during a period of several weeks in the application of this method of treatment.

In view of this, the writer unhesitatingly recommends the serious consideration of these statistical findings on the part of everyone concerned in the problem of schizophrenia. When, as it appears from these statistics, as many as over three-fourths of the patients who had been ill less than half a year, make complete recoveries, and over sixty-eight per cent of those who have been ill less than one and a half years are similarly benefited, it would appear reasonable to subject every new case of schizophrenia to this form of therapy, even though we know that some of these cases would have made a spontaneous recovery. This attitude seems to the writer entirely justified, notwithstanding the fact that the treatment in question is not entirely free from danger, and that as far as is known, four deaths have occurred in over 300 patients who have undergone this treatment.

At the Cantonal Hospital (Münsingen, Switzerland) where about fifty patients received this treatment during the past year, no serious complications have occurred, and a close study of their staff and ward organization and of the technic strictly insisted upon at this institution, will convince anyone that the danger connected with this method of treatment need not be unmanageable. It is true, however, that the therapeutic method under consideration requires a degree of competence, vigilance, and conscientious attention to minute detail second to none in the entire medical and surgical and psychiatric technic of contemporary medicine. The method is also quite expensive, owing to the large amount of insulin employed, and especially because of the demands it makes upon medical and nursing facilities. Certainly, it cannot be employed outside of a well-organized sanatorium or hospital regime. But when one keeps in mind the medical and social-economic stature of the problem of mental disorder and the share contributed to this problem by the schizophrenias, the difficulties and the dangers of this therapeutic method should be no deterrent to its wide employment at the hands of adequately trained people. Apart from the immediately practical consideration of the promise of checking the trend to chronicity in schizophrenia, and time alone will tell the final story in this regard, this new biochemical approach to psychopathology opens up a great variety of theoretical problems of great significance which might well engage the best minds in the field of biochemical and psychobiological research.

The therapy under consideration con-

marked excitement, another injection of the same dose of insulin is administered at 2 P M, but the neutralizing carbohydrates are administered two hours later. The initial dose is then increased daily by five to ten units, six days a week, followed by the so-called rest-day when the treatment is omitted. In the course of this phase 1, the hypoglycemia manifestations begin to appear and, usually, with increasing severity. They consist in a profuse sweating, (large drops) increased flow of saliva of a peculiarly viscid type, yawning, and tremor. Later on in this phase, there frequently appear clonic twitchings of the musculature of the extremities, shoulder girdle, and face. Subjectively, the patients experience a certain sedative feeling, a pleasant feeling of warmth throughout the body, slight paresthesias in the fingertips, palms of hands, and around the mouth. Occasionally they complain of a slight anxious, oppressed feeling around the heart, pounding of the heart, and double vision. How far this first phase has to be carried until the second phase is reached is subject to great variations. Patients have been known to pass into profound coma after the administration of only twenty units of insulin, indeed, one patient had an epileptic seizure after twelve units. On the other hand, the writer observed one patient who failed to show the slightest physical or psychic signs of hypoglycemia after repeated injections of as many as 240 units of insulin. Apart from the well-known fact of the individual differences in sensitivity to insulin, the differences in the symptoms which appear in the hypoglycemic state seem to determine the degree of reactivity of the insulin antagonists, (adrenalin, pituitrin) which affects in turn the progress of the hypoglycemic state. Thus, in cases with considerable muscular irritability and excitement, there is probably a greater tendency towards an adrenalin neutralization of the effects of the insulin. There are, however, differences of opinion as to whether or not an attempt should be made to eliminate this muscular excitation through the administration of sedative drugs, as exist also marked differences of opinion with reference to one's attitude towards a threatening epileptic seizure. Müller³ is of the opinion that the patients are able to exercise considerable volition

in the matter of permitting themselves to sink into the deeper phases of the hypoglycemic state. According to Sakel, old cases of schizophrenia seem to be more resistant to the influence of insulin than recent cases. Indeed, he carries this contention to the point of claiming to be able to tell the duration of a schizophrenic disorder from the patient's responsiveness to the insulin. At any rate, whether or not the patient shows any obvious reaction indicative of the hypoglycemic state, the individual treatment *must always be followed by the introduction of the appropriate amount of carbohydrates*.

Phase 2 The precise point of transition from phase one to phase two is to a large extent arbitrarily determined. One deals here with the so-called shock-phase, the most important stage in the treatment. In practice, this stage is assumed to have been reached when the dosage of insulin produces a degree of coma which no longer enables the patient to drink the sugar solution voluntarily and nasal tube-feeding has to be resorted to. Or, irrespective of the degree of coma and other manifestations of a deep hypoglycemic state, the patient is threatened with a convulsive seizure. While the ordinary shock has been designated "wet-shock," because of the profuse sweating which accompanies it, Sakel is of the opinion that those patients are most likely to develop an epileptic seizure who do not show the customary evidences of a wet-shock. Indeed, they frequently show very few signs of a hypoglycemia until the epileptic seizure suddenly sets in.

It is in this phase of the treatment that one must be ready for emergency intervention, either through the intravenous administration of a thirty-three to forty per cent glucose solution (at times as much as 150 to 180 c c before the hypoglycemia is neutralized), or in addition, also, through the hypodermic administration of adrenalin and at times, of cardiac and respiratory stimulants. The nasal administration of an adequate amount of sugar must, nevertheless, also be carried out. When the patient reaches this shock phase, the somnolence passes into a coma of greater or less depth, the normal reflexes become abolished, pathological reflexes take their place (Babinski, Oppenheim, etc.) and finally there sets

sists in a progressive insulinization of the patient through the daily, intramuscular injection of increasing doses of insulin until the so-called shock-dose is reached in the individual case. Each daily insulinization is, of course, neutralized after the lapse of a period of time required by the individual case through the administration of an adequate amount of carbohydrates. Thus, it happens that the daily observation of as few patients as fifteen (which is about the maximum number that two physicians can properly attend to at one time) furnished in the course of even a very few weeks an uncommonly rich and concentrated clinical experience with the hypoglycemic state, with its great multiplicity of vegetative, neuromuscular, and psychic phenomena. Apart from this, this experience derives an extraordinary uniqueness from the fact that this wealth of clinical pathology is experimentally provoked and abolished at will, so that one gains an impression of the organism's capacity for a reversibility of its reactions, quite unknown in connection with ordinary, physiological, psychological or medical experience. Patients who, a few minutes before the introduction of the neutralizing carbohydrates, were in a state of most profound somatic and psychic disorganization—indeed, one might say, disintegration—begin to change before one's eyes as soon as the introduced sugar begins to be absorbed, and exhibit a gradual, progressive reintegration, often followed by a more or less complete amnesia for everything that transpired during the hypoglycemic state. Close observation of the patient from the onset of the hypoglycemic state on through to complete recovery from it, leaves no doubt about the fact that the entire phenomenon of vegetative and cerebrospinal and psychic morbidity and subsequent recovery is governed by a definite orderliness which derives from the phylogenetic and ontogenetic organismal experience. This fact is of great significance in connection with any endeavor to furnish a theoretical explanation of the dynamics and the *modus operandi* of this therapy and will be discussed in greater detail later in this paper.

II

From a historical standpoint, it should

be stated that the application of this treatment to the schizophrenias developed purely empirically as an outgrowth of Sakel's original employment of insulin in the management of the withdrawal symptoms in morphine addicts.² In connection with this, Sakel observed that the occasionally unavoidable hypoglycemic states which developed in these patients in spite of the fact that the administration of the insulin was accompanied by the simultaneous administration of carbohydrates, had a distinctly quieting effect on motor excitements. He then extended the application of this treatment to various forms of schizophrenic disorders and made the significant discovery that the very condition which one aims to avoid in connection with the insulin therapy of diabetes mellitus, namely, the insulin-shock, proved to be of benefit in the treatment of schizophrenics.

As originally described by Sakel, the treatment consists of four phases, the duration and intensity of each phase being strictly graduated in accordance with the requirements of the individual case. This point cannot be stressed too strongly. The most difficult aspect of the entire procedure is the total unpredictability of the reactions to the hypoglycemic state in different patients, and in the same patient from day to day. While a strict adherence to the minutiae is essential, a free elasticity must, nevertheless, be permitted in order to meet the requirements of the frequently changing indications. Experience alone with the artificially induced hypoglycemic state, in addition to a thoroughgoing acquaintance with the somatic and psychic characteristics of the individual patient are the most dependable guides in this connection.

Phase 1 An initial, intramuscular injection of between twelve to twenty units of insulin, depending on the body-weight and general physical status of the patient is given on an empty stomach between 7 and 7 30 in the morning. The patient is kept in bed, and four to five hours later is given from 150 to 200 gms of sugar in tea, water or milk by mouth, and shortly afterward, his regular mid-day meal. During the rest of the day, the patient is permitted to carry on the usual hospital routine, unless prevented from doing so by certain special conditions. In case of

marked excitement, another injection of the same dose of insulin is administered at 2 P M, but the neutralizing carbohydrates are administered two hours later. The initial dose is then increased daily by five to ten units, six days a week, followed by the so-called rest-day when the treatment is omitted. In the course of this phase 1, the hypoglycemia manifestations begin to appear and, usually, with increasing severity. They consist in a profuse sweating, (large drops) increased flow of saliva of a peculiarly viscid type, yawning, and tremor. Later on in this phase, there frequently appear clonic twitchings of the musculature of the extremities, shoulder girdle, and face. Subjectively, the patients experience a certain sedative feeling, a pleasant feeling of warmth throughout the body, slight paresthesias in the fingertips, palms of hands, and around the mouth. Occasionally they complain of a slight anxious, oppressed feeling around the heart, pounding of the heart, and double vision. How far this first phase has to be carried until the second phase is reached is subject to great variations. Patients have been known to pass into profound coma after the administration of only twenty units of insulin, indeed, one patient had an epileptic seizure after twelve units. On the other hand, the writer observed one patient who failed to show the slightest physical or psychic signs of hypoglycemia after repeated injections of as many as 240 units of insulin. Apart from the well-known fact of the individual differences in sensitivity to insulin, the differences in the symptoms which appear in the hypoglycemic state seem to determine the degree of reactivity of the insulin antagonists, (adrenalin, pituitrin) which affects in turn the progress of the hypoglycemic state. Thus, in cases with considerable muscular irritability and excitement, there is probably a greater tendency towards an adrenalin neutralization of the effects of the insulin. There are, however, differences of opinion as to whether or not an attempt should be made to eliminate this muscular excitation through the administration of sedative drugs, as exist also marked differences of opinion with reference to one's attitude towards a threatening epileptic seizure. Müller³ is of the opinion that the patients are able to exercise considerable volition

in the matter of permitting themselves to sink into the deeper phases of the hypoglycemic state. According to Sakel, old cases of schizophrenia seem to be more resistant to the influence of insulin than recent cases. Indeed, he carries this contention to the point of claiming to be able to tell the duration of a schizophrenic disorder from the patient's responsiveness to the insulin. At any rate, whether or not the patient shows any obvious reaction indicative of the hypoglycemic state, the individual treatment *must always be followed by the introduction of the appropriate amount of carbohydrates*.

Phase 2 The precise point of transition from phase one to phase two is to a large extent arbitrarily determined. One deals here with the so-called shock-phase, the most important stage in the treatment. In practice, this stage is assumed to have been reached when the dosage of insulin produces a degree of coma which no longer enables the patient to drink the sugar solution voluntarily and nasal tube-feeding has to be resorted to. Or, irrespective of the degree of coma and other manifestations of a deep hypoglycemic state, the patient is threatened with a convulsive seizure. While the ordinary shock has been designated "wet-shock," because of the profuse sweating which accompanies it, Sakel is of the opinion that those patients are most likely to develop an epileptic seizure who do not show the customary evidences of a wet-shock. Indeed, they frequently show very few signs of a hypoglycemia until the epileptic seizure suddenly sets in.

It is in this phase of the treatment that one must be ready for emergency intervention, either through the intravenous administration of a thirty-three to forty per cent glucose solution (at times as much as 150 to 180 c.c. before the hypoglycemia is neutralized), or in addition, also, through the hypodermic administration of adrenalin and at times, of cardiac and respiratory stimulants. The nasal administration of an adequate amount of sugar must, nevertheless, also be carried out. When the patient reaches this shock phase, the somnolence passes into a coma of greater or less depth, the normal reflexes become abolished, pathological reflexes take their place (Babinski, Oppenheim, etc.) and finally there sets

in a total abolition of all reflex activity. Occasionally one observes a transitory hemiplegia, which, like the aphasia that may develop on awakening, disappears after a short time. It is in connection with these manifestations that one can observe the greater vulnerability of the dominant hemisphere. Pallor, tachycardia, sometimes marked bradycardia, fluctuations in blood pressure, disturbances in respiration, marked twitchings, and clonic movements of a coarser type, sometimes very marked tonic attitudes and movements reminiscent of the behavior of the decerebrated animal, can also be observed. Of particular interest and significance are manifestations during this phase in the nature of an acting out and living out of tendencies which seem to have a distinct bearing on the content of the patient's psychosis. The most difficult point in the entire treatment is the determination of how long to keep the individual patient in this condition of insulin shock. On the one hand, it is desirable to maintain this stage as long as possible, since it seems to be the profundity and duration of the coma and the intensity of the affective reaction that determines the therapeutic progress. On the other hand, the patient's physical condition may demand the immediate neutralization of the hypoglycemic state, irrespective of the requirements of the therapy of the mental condition. Under ordinary conditions, the patient awakens within five to fifteen minutes after the sugar solution reaches the stomach, in rare instances, especially where the shock has been protracted, within half an hour. The intravenous administration of glucose usually produces the desired effect immediately. There is no general rule as regards the number of shocks the individual patient has to experience. Patients have received as many as forty and more shock treatments. One is naturally guided here by the progress of the improvement in the individual case. The question as to when one can definitely state that the patient happens to be one who cannot be influenced by the insulin therapy, is still an open question demanding much more experience than is at present available for a definite answer.

Before proceeding to a consideration of phases three and four, reference should be made to Sakel's latest paper,⁴ in which

he attempts to formulate more precise rules for the administration of the treatment in each of the three types of schizophrenia which he recognizes, namely, the paranoid, catatonic, and the catatonic excitement. He calls attention again to his hypothesis that the hypoglycemia suppresses the momentarily most active part of the psyche, and thus makes possible the emergence of the latent aspects thereof, which then supplants to a greater or less extent the acute existing manifestations which have already been repressed by the insulin. One might visualize the situation somewhat as follows: before the stage of complete coma is reached, the hypoglycemia inhibits and delimits the existing (psychotic) state and converts it into its opposite (insofar as one might speak at all of opposites).

He maintains that he has actually been able to observe in many, if not all cases, that a hallucinated and delusional patient would, for instance, manifest a brief period of complete lucidity just before falling in a deep coma. The same patient later on, after the improvement had progressed far enough to enable him to behave quite normally when not in the hypoglycemic state, will during the shock become acutely psychotic again for a brief period before sinking into deep coma. He calls this the activated psychosis. He further refers to the strong tendency to the fixation of the condition which exists at the time of the interruption of the hypoglycemia. In the main, this refers to conditions of passivity and activity, of excitement and calm. Thus the interruption of the shock in the case of an excited catatonic during a state of calm and passivity would tend to establish a similar condition, also, for the non-hypoglycemic phases. Conversely, in the case of a stupor, the interruption of the shock during a state of activity and excitement, would tend to continue to activate the patient outside of his hypoglycemic state. He accordingly stresses very much the importance of determining the most advantageous moment for interrupting the shock. On the basis of the foregoing considerations, he advises the following procedure in the three different types of schizophrenia.

1 For those cases which are predominantly paranoid in character, the original

technic continues to hold good, inasmuch as the hypoglycemic state is permitted to reach a degree of deep coma and the shock is never interrupted during the manifestation of an activated psychosis, unless the physical condition of the patient calls for an interruption. The aim here is essentially as complete as possible a suppression of the existing psychotic state and the favoring of as complete an amnesia as possible.

2 In the case of patients who are predominantly stuporous, the aim should be during the first part of the second phase of the therapy to determine the best moment for the interruption of the hypoglycemia, namely, at the first indications of an activation either in the form of some release phenomenon or an excitement, in order to establish a condition which is as much as possible in contrast to the existing stupor. Should the signs of an activation be overlooked and the patient permitted to sink into a deeper coma, it may result in definite harm to the patient.

The foregoing remarks, however, must not be taken too literally, since stuporous patients have been known to recover only after experiencing states of deep coma. It may be that one is dealing here with types of stupor which depend more on active hallucinatory and delusional factors than on inhibitory factors. Owing to the much greater difficulty in treating these patients, it might be well to quote Sakel's instructions regarding these cases verbatim. He says

We begin with fifteen to twenty units and increase by five to ten units daily. The fundamental difference in method between these patients and the paranoid types is that these patients must be most carefully observed for signs of activation. When these evidences of activation occur, the problem is to determine the most favorable moment in the individual case for the termination of the shock. The insulin dose should be, if possible, the shock-dose, that is, sufficiently adequate to lead to a deep coma if the patient were permitted to reach this stage.

This activation may manifest itself in various ways. It may begin with slight indications of release, which become more marked from day to day, it may be initiated in the form of a more or less complete awakening, or it may take the form of an emergence of a delusional or hallucinatory content which had hitherto been kept in subjugation by the stupor, thus converting a non-productive psychosis into a productive one. All these various manifestations were found to be more favorable for the future

course of the psychosis than the stupor. The further progress of the treatment consists in an endeavor to convert the stupor into a productive psychosis and to fixate the same. After this newly achieved situation continues to manifest itself in the non-hypoglycemic state of the patient, he can then be subjected to the deeper phases of the shock—the coma—as in the case of the paranoid patient. It should be, furthermore, added that whereas in the case of the paranoid patient we endeavor to eliminate every possible external stimulus during the hypoglycemic state (in order to avoid adrenalin neutralization²), we do not follow this rule in the case of the stupor. On the contrary, we stimulate the patient through questioning him, shaking him, and in various other ways which might favor the secretion of adrenalin.

Sakel also cautions here not to take the foregoing suggestions too literally, but to rely on such hints as the individual patient may furnish.

As regards the catatonic excitements he states that from the very beginning he and his associates were impressed with the fact that this type of patient did not respond as favorably as the others to the deep hypoglycemic state. Neither did the course of the disorder during the treatment show the regularity of progression as in the other cases. It was very difficult in these cases to maintain the progress achieved, the patients repeatedly showing relapses, in contrast to the paranoid patients where one could with certainty maintain that the progress made would be retained. He proceeds in treating this type of patient by starting as in the others with fifteen to twenty units, but in contrast to the others, he administers this dosage two or three times daily (with proper interruptions as already indicated) because of the need of quieting the excitement. The dose is increased daily by five to ten units. When the patient quiets down, the hypoglycemia is induced only once daily and during the early stages in the treatment is terminated through the mere administration of food, later through the usual administration of sugar. When the shock-dose is reached, that is to say, a dose adequate to produce deep coma after a maximum of five hours, the difficult task begins of determining precisely the duration of the shock. The most favorable point for interruption seems to be the moment of maximum somnolence, and just before the patient sinks into a deep

coma In general, coma should be avoided in these cases and an effort should be made through active urging of the patient to make him drink the sugar solution The difficulty here lies in the administration of the sugar solution, that is in the necessity of avoiding the excitement and exertion incident to nasal feeding in a patient who is not sufficiently comatose and who is, nevertheless, in such a state of somnolence that he cannot be persuaded to drink the solution, or perhaps is actually already unable to perform the act of swallowing

The excitement incident to the nasal feeding in these patients who are still capable of resisting the procedure, seems to be very detrimental to the general course of the treatment and should be avoided whenever possible, even at the expense of permitting a patient to sink into a deeper state of coma than is otherwise desirable One sees, therefore, how much more difficult the treatment of these patients is in comparison with the other types This accounts also for the fact that the results are not as favorable here as in the paranoid and stuporous patients

Phase 3 This is merely a transition stage between 2 and 4, and is really limited to a designation of the usual and the occasionally unavoidable rest periods in the treatment, that is the usual seventh day each week, and such other interruptions as are called for because of intercurrent febrile and other somatic disorders After an epileptic seizure, the patient is usually allowed two or three days freedom from treatment

The duration of the second phase, as has already been indicated, must be adjusted to the requirements of the individual case, essentially until the psychotic manifestations both in and outside of the hypoglycemic state have disappeared It should also be mentioned at this point that while the shock-dose once reached should be maintained throughout the second phase, it sometimes happens that the patient develops an insulin sensitization and the same effect can be produced with much smaller doses

Phase 4 This only refers to the cases in which the preceding treatment led to the desired result, a remission of all symptoms, and is supposed to serve as a means of consolidating and stabilizing the gains

achieved Much smaller doses of insulin are administered than in phase two, ten to thirty units, and the carbohydrates are administered no later than two hours after the insulinization Naturally, the patient is not permitted to reach a deep state of shock The treatment is continued until the patient's discharge from the institution

III

As has already been stated, this therapy is not without danger, but last year's experience at Munsingen proves without much doubt that these dangers can be entirely obviated or certainly reduced to a minimum when proper precautions are taken Müller, in discussing this phase of the subject in the paper already referred to, says

The administration of the insulin therapy is rendered difficult not only because of the individual variations in sensitivity to this agent, and a sensitization which frequently occurs in the course of the treatment, but also because of the fact that our knowledge concerning the genesis of the initial hypoglycemic manifestations as well as of the insulin shock is very inadequate. Certainly, no direct relationship exists between the tangible, clinical manifestations of the hypoglycemic state and the actual blood-sugar state To be sure, a drop of the blood-sugar to below 60 mg per cent is an essential precondition for a clinical reaction On the other hand, one repeatedly sees cases in whom a drop of the blood-sugar to 30 mg per cent, and lower, gives rise to no clinical manifestations In these cases, the clinical manifestations set in only after the administration of much larger doses of insulin, which, however, does not cause a further drop in the blood-sugar content Furthermore, the deepest stage of insulin shock does not at all necessarily correspond with the lowest point in the blood-sugar content, on the contrary, the blood-sugar begins to rise at this particular point in most cases Thus, the blood-sugar picture furnishes no indication as to the kind of clinical manifestations one might expect. Most likely it seems to be the case that a large part of the hypoglycemic symptoms are due not to the hypoglycemia as such, but to the reaction to it, that is, to the compensatory secretion of adrenalin, whether this be considered as primarily toxic or secondarily conditioned by the hypoglycemia. According to Kugelman, the pounding of the heart, tremor and sense of oppression are adrenalin symptoms, whereas the weakness and sweating are the

direct result of the hypoglycemia. The spasms probably also belong to the adrenalin manifestations. Other authors attribute this to the low sugar content of the spinal fluid. Unger believes this to be due not so much to the low sugar-content as to the rapidity of the drop.

Naturally, one deals with serious matters where it concerns the profound comatose shock as well as the epileptic seizure. In addition, there is the possibility of a number of other unpleasant albeit less frequent complications, such as collapse, glottal spasm, vomiting during the state of unconsciousness, with the danger of aspiration. The possibility of the so-called after shock should likewise not be neglected. One has to deal here with a spontaneously developing hypoglycemia which sets in a number of hours after the induced hypoglycemia had been properly neutralized by the administration of carbohydrates. It is to be expected that it is more likely to occur in cases where part of the administered carbohydrates has been lost through vomiting. In the single instance of this character which occurred at Münsingen, the carbohydrates were administered at 11.30 A.M. without any unusual difficulty. The patient felt entirely well during the afternoon, but at 7 in the evening he sank into a profound comatose state with severe twitchings of the muscles, which demanded the immediate intervention with adrenalin and intravenous glucose.

In view of the experiences of internists in connection with spontaneous hypoglycemia in the treatment of diabetes, the condition of the heart deserves particular attention. One notices almost regularly in the course of the hypoglycemia, a rise in blood pressure (usually an increase in systolic and slight drop in the diastolic). Very frequently, furthermore, there occurs a tachycardia up to 120, which occasionally persists for a number of hours, even until the evening, but which regularly disappears by the following morning. Much more rarely one observes a bradycardia. Apart from this, no other clinical manifestations of cardiac disorder could be established. On the other hand, Chatel and Palisa were able to demonstrate slight cardiographic changes in connection with the Vienna material, but they attributed no significance to this.

Hadorn carried out a much broader investigation along these lines in connection with the clinical material at Münchenbuchsee, as well as on animals. He was able to demonstrate definite electrocardiographic changes, which were, however, reversible, so that no direct damage to the heart as result of the individual shock could be established. Nevertheless, he leaves the question of the possi-

bility of a lasting injury to the heart undecided, and stresses the point that the circulatory system must be most carefully watched during the insulin therapy, not only in those actually suffering from heart disease but also in every patient falling within the arteriosclerotic period of life. In this connection, one might also refer to the experiments carried on by Schmid, who subjected animals to an insulin therapy similar to the one under consideration and found only slight reversible cerebral damage even after repeated epileptic seizures.

In view of the obscurity which still surrounds some of the basic issues involved in this entire question, any theoretical explanation of the dynamics and *modus operandi* of this therapy must be highly tentative in nature. Nevertheless, it is decidedly helpful to have some working hypothesis in mind, even though a more dependable factual experience might call for radical modifications of theory in the future. Sakel adheres strictly to a biochemical hypothesis which he endeavors to sum up in the following three propositions.

- 1 The insulin puts a barrier between the cell and external stimuli, thus putting the cell at rest and enabling it to recuperate. He assumes that by keeping the pathologically conditioned cell-pathways in abeyance, the original, normally conditioned pathways have a chance to re-establish themselves.

- 2 The profound, almost annihilating assault which the cell experiences during the insulin shock perhaps actually eliminates the recently established pathological pathways, and in the course of recovery from the shock, only the older, well-established pre-psychotic pathways become re-animated.

- 3 A general detoxication of the entire organism through the effect of the insulin on the entire metabolic status.

He bases these generalizations on a theory of cell activity which he originally propounded in connection with the application of insulin to the management of the withdrawal symptoms in morphine addicts. We cannot submit here a detailed statement of this theory. This much, however, must be at least indicated namely, that he assumes a progressive development in the cell of pathways which are specific to certain stimuli. There develops in time a sort of hierarchy of pathways, the older in time of origin naturally being the more resistive to insult. Through the elimination of

the existing contemporary pathological pathways, the older, normal ones have a chance to reassert themselves and adaptation to reality becomes normal again. I hope, in this greatly abbreviating what he says in the theoretical portion of his publications, I am not misquoting him. At any rate, whatever he has to say theoretically is prefaced by unmistakable assertions concerning the tentativeness of its nature.

IV

The writer has no definite opinion concerning the degree of validity of Sakel's theoretical views. He has a strong urgency, however, to express, very tentatively, to be sure, some general impressions gained from observing these patients in the insulin shocks, and certain thoughts to which these impressions give rise. The great play of phenomena of disorganization and reorganization which passes before one's eyes in observing these patients impresses one not only with the orderliness in the appearance and disappearance of these manifestations already alluded to, but also with the great vulnerability of the organism in the course of the hypoglycemic state. Perhaps it should be designated as a great impressionability, the patients clinging to those who first come within their vision like helpless children. It is this fact which probably accounts also for the rapid improvement in the accessibility and transference capacity of the schizophrenics under this treatment, a phenomenon observed by every investigator and particularly stressed by Bychowski in his paper before the recent Psychoanalytic Congress at Marienbad. It is apparent that this state of heightened impressionability and suggestibility is of great significance, negatively as well as positively. Patients who had made considerable progress towards recovery have been known to experience a serious setback in consequence of psychic traumata encountered during this period. It is conceivable that the opposite is also true, namely, that this phase can be exploited to the patient's benefit through proper suggestions.

Sakel repeatedly stresses the importance of psychic factors during the stage of convalescence, and the writer has convinced himself to his own satisfaction that although this therapeutic approach

is essentially of a biochemical nature, its effects insofar as they lead to a modification of psychopathological states can in no way be looked upon as identical with those characteristic of a strictly causal therapy, such, for instance, as the psychoanalytic therapy of a hysterical phobia. On the contrary, one gains the impression of a radical and fairly rapid generalized disturbance of the vegetative, neurological, and psychic integration of the patient which calls forth in its turn a rapid reintegration immediately upon the neutralization of the hypoglycemia. But in addition to the important role which the sugar metabolism plays in this catabolic and anabolic process, psychic factors seem also to be of considerable significance.

Thus it is highly significant that in addition to the orderliness in the appearance and the disappearance of the morbid manifestations already alluded to, the impression is inescapable that the reactions which these patients show in the hypoglycemic state are not altogether meaningless from the point of view of the nature and content of the psychosis for which the patient is being treated. It seems as though the hypoglycemic state not only creates general conditions for a new reintegration but that within the scope of this general preparedness there is a possibility for a more specific settlement of certain organismal or perhaps personality problems and for a more specific reorientation to reality. From the relatively great multiplicity of clinical observations which lead me to this impression, (in the course of one month I was able to observe about 400 hypoglycemic states in about twenty patients) I will mention a few as illustrative of the point I am endeavoring to make.

CASE 1 A woman in her early thirties, whose paranoid schizophrenia was of about two years' duration, was admitted to the hospital in a delusional and hallucinated state, and showed in addition a particularly morose, angry, negativistic, and suspicious demeanor which rendered her quite wholly inaccessible. She shunned every contact with others and spoke with a peculiarly distorted intonation and articulation so that she could hardly be understood. The general impression she made was that of an angry, melancholy patient with irritability and moroseness, and extreme physical and

psychological tenseness During one of her very earliest hypoglycemic states she became hilariously excited, laughed and shouted and threw herself about in bed in a wholly abandoned manner, calling for champagne, unconcerned about exposing herself, and what was particularly impressive was that for the first time she abandoned her peculiar articulatory and tonal distortion, and spoke clearly and accurately, although in a somewhat childishly coy manner On awakening, she had a total amnesia for what had transpired, but was noticeably less negativistic and more approachable. She repeated this performance with slight variations in the degree of abandon several days in succession during the hypoglycemic states, and the impression as one watched her was inescapable that she was having a very good time, indeed, during these states of abandon and release Coincident with this, her attitude and demeanor during the non-hypoglycemic periods showed very definite improvement

CASE 2 A young girl who gradually developed a catatonic stupor preceded by vague delusional and hallucinatory preoccupations, and whom it was my privilege to observe almost from the very beginning of the treatment until she was discharged with a good remission three weeks later, exhibited for a number of days within the hypoglycemic state a most intense oral preoccupation Beginning with an ordinary Schnautzkrampf, her lips, tongue, and cheeks would then become engaged in a most extraordinary exploitation of sucking of tongue, smacking of lips, evertive and invertive movements of lips, which would go on for an hour or two while she was in a state of profound unconsciousness In addition to this, an occasional aggressive attitude was noticeable, especially of fists and arms, and on several occasions upon awakening, she actually had brief outbursts of combativeness Neither in her prepsychotic state, nor during her psychosis did this patient show the slightest tendency to aggressiveness or combativeness On the contrary, according to her mother's statement, she was always of a meek, submissive nature, carrying willingly more than her share of work at home and later at a hotel where she was employed up to the onset of her illness

In both of the above patients the hypoglycemia released activities of a highly emotional coloring which were foreign to the patients' usual state, but which unquestionably constituted an element in the background of the patient's psychosis

CASE 3 An intensely paranoid, young German Jew, the content of whose psychosis was largely concerned with the current Jewish situation in Germany, was observed in a Swiss private sanatorium during practically a whole hour in an almost unbelievably intense sadistic-aggressive state of muscular thrashing about, gnashing of teeth, angry facial distortion and angry grunting, requiring the services of two attendants to keep him in bed, all of this in a state of complete unconsciousness On awakening after the administration of carbohydrates, he exhibited a happy, slightly hilarious attitude and reiterated several times "Don't you think I'm brave, I know I am brave." Soon afterwards, he was quite natural in his demeanor, had a complete amnesia for his activity during the hypoglycemia, and I was told by his physician that he has been showing marked improvement coincident with the intensity of his hypoglycemic discharges

The writer has had many occasions in the past to defend the principle of teleology in the manifestations of the psychotic, but only rarely was he more strongly impressed with the quality of meaning and purpose than in the reactions of some of these patients while in a profound state of unconsciousness during the hypoglycemia

CASE 4 An intensely severe compulsion-neurotic, whose neurosis has existed for over thirty years and whose confinement to a sanatorium became unavoidable because of the complexity and extent of his defensive maneuvers in speech and action, was observed just as he was emerging from the hypoglycemic state. His facial expression of bewilderment and intense fear denoted unmistakably a state of profound anxiety Shortly afterwards, when he had completely attained his normal state of consciousness, he was asked to describe his state of anxiety He was a very intelligent person, and he drew a most interesting distinction between the anxiety he had been thoroughly familiar with in the course of his compulsion-neurosis and this "deadly indescribably painful, panicky helplessness" which went with the hypoglycemic anxiety Is it not conceivable that his customary, life-long neurotic anxiety, to the management of which he has devoted practically a lifetime of thought and energy, might experience quite a deflation when exposed to a comparison with the repeated states of real anxiety of this most intense nature which he experiences during the hypoglycemia?

At any rate, this patient is showing in his free periods a rather interesting turn of

the existing contemporary pathological pathways, the older, normal ones have a chance to reassert themselves and adaptation to reality becomes normal again. I hope, in thus greatly abbreviating what he says in the theoretical portion of his publications, I am not misquoting him. At any rate, whatever he has to say theoretically is prefaced by unmistakable assertions concerning the tentativeness of its nature.

IV

Sakel repeatedly stresses the importance of psychic factors during the stage of convalescence, and the writer has convinced himself to his own satisfaction that although this therapeutic approach

is essentially of a biochemical nature, its effects insofar as they lead to a modification of psychopathological states can in no way be looked upon as identical with those characteristic of a strictly causal therapy, such, for instance, as the psychoanalytic therapy of a hysterical phobia. On the contrary, one gains the impression of a radical and fairly rapid generalized disturbance of the vegetative, neurological, and psychic integration of the patient which calls forth in its turn a rapid reintegration immediately upon the neutralization of the hypoglycemia. But in addition to the important role which the sugar metabolism plays in this catabolic and anabolic process, psychic factors seem also to be of considerable significance.

Thus it is highly significant that in addition to the orderliness in the appearance and the disappearance of the morbid manifestations already alluded to, the impression is inescapable that the reactions which these patients show in the hypoglycemic state are not altogether meaningless from the point of view of the nature and content of the psychosis for which the patient is being treated. It seems as though the hypoglycemic state not only creates general conditions for a new reintegration but that within the scope of this general preparedness there is a possibility for a more specific settlement of certain organismal or perhaps personality problems and for a more specific reorientation to reality. From the relatively great multiplicity of clinical observations which lead me to this impression, (in the course of one month I was able to observe about 400 hypoglycemic states in about twenty patients) I will mention a few as illustrative of the point I am endeavoring to make.

CASE 1 A woman in her early thirties, whose paranoid schizophrenia was of about two years' duration, was admitted to the hospital in a delusional and hallucinated state, and showed in addition a particularly morose, angry, negativistic, and suspicious demeanor which rendered her quite wholly inaccessible. She shunned every contact with others and spoke with a peculiarly distorted intonation and articulation so that she could hardly be understood. The general impression she made was that of an angry, melancholy patient with irritability and moroseness, and extreme physical and

their experiences After interviewing a fairly large number of recovered patients, one gains the impression that these recoveries divide themselves roughly into two types, the one with a distinct emphasis on the virtues of repression, and the other with a definite preference for the so-called working through and reintegration

Be that as it may, the foregoing tentative theorizing suffers a good deal from the fact that patients have been known to recover in consequence of the insulin therapy, whose hypoglycemic state had never reached the profundity of coma, and had never given rise to any of the expressive phenomena mentioned above The only things these patients had in common with the others who did show the more profound reactions was the hypoglycemia. How is one to interpret the therapeutic dynamics here? Wilder in a recently published monograph which has for its aim a delineation of the disease-entity "Zuckermangelkrankheit" (sugar starvation disease) gives ample evidence of the many problems which still remain unsolved in this field To be sure, he deals primarily with the so-called spontaneous hypoglycemia But the situation cannot be much different in those deliberately induced What is undeniable in both cases is the profundity and gravity of the assault upon the organism of an extensive and sudden sugar deprivation It is to be expected that in the case of the spontaneous hypoglycemia, because of the organism's greater opportunity for neutralizing efforts, the assault is not likely to be as grave as in the case of the sudden draining of the organism's sugar through the sudden and unexpected introduction of large quantities of insulin It is likewise to be expected that such an event, in addition to provoking the consequences of a sugar drainage, should also stimulate a sudden mobilization of the available forces by way of the endocrinal antagonists to insulin (adrenalin, pituitary), which in its turn adds to the organism's capacity to control and master impulses

Whatever one's leanings may be regarding the pathogenesis of the so-called functional psychoses, there can be no difference of opinion regarding the central therapeutic aim in these disorders One strives to bring about in these patients such changes in the personality (ego) as

will enable it to control more efficiently its impulses Even a protracted and deep psychoanalysis aims ultimately at such a strengthening of the ego Speaking strictly psychiatrically, one aims at a better and more accurate understanding of his difficulties on the part of the patient and at a greater adjustive capacity Perhaps this repeated, profound assault on the organism through depriving it of its sugar actually does lead to a kind of reconstructive effort, perhaps by way of a hormonal rearrangement, the result of which is a strengthening of the organism's capacity for meeting the requirements of biological and social living The fact remains, that some patients do achieve excellent recoveries (I have in mind particularly two female patients whom I had the privilege to examine thoroughly) without exhibiting any of the dramatic manifestations of the hypoglycemic state mentioned

But when this factor of a strengthening of the ego in the manner described above is taken together with the other factors of repression and catharsis which the hypoglycemic state appears to favor, I think a fairly suggestive theory is at hand for the explanation of the therapeutic effects of the insulin therapy The entire situation might then be viewed as a highly condensed recapitulation of the process by means of which the fate of ego-dystonic impulses is determined, a process which takes place normally, in the course of ontogenetic development, and artificially, in the course of a psychoanalytic therapy

If the above theoretical considerations have any validity, at all, at least two highly significant conclusions must follow In the first place, the therapy should be designated a cellular therapy instead of a therapy of schizophrenia There already exists some evidence of the therapeutic worth of this therapy in psychopathological disorders other than schizophrenia (compulsion-neurosis, depressive states, acute undifferentiated excitements, certain addictions) In the second place, while it is true that the therapeutic means is of a strictly biochemical nature, the process depends to a high degree for its success upon a nicety of psychological management Even in connection with the primary task of determining the extent and depth of the hypoglycemic state in individual patients from day to day a thorough

events On the one hand, he is not so intensely dominated by his compulsive thoughts and actions as formerly, while on the other hand he writes the most unbelievably childish letters to his wife, productions which viewed in the light of the fact that he is actually an exceedingly intelligent man, has a mastery of several languages, and was at one time manager of a large Swiss hotel, must certainly denote a profound, though perhaps selective state of regression.

The question which forces itself on one's mind in this connection is whether in the compulsive-neurotic type of individual a preliminary transitory state of regression similar to the schizophrenic's but perhaps accompanied, because of the nature of the individual, by a good deal more anxiety, is a necessary precondition for recovery One recalls in this connection Freud's often reiterated contention that a psychoanalytic therapy can only be carried out successfully in a state of denial and privation In comparison with the depth and significance of the privation due to the sudden drainage of the organism of its sugar content through the introduction of large doses of insulin, the privations incident to a psychoanalysis certainly seem insignificant Perhaps a greater clarification of the issues involved in this therapy might result if one were to shift one's position from a concentration upon detail to one which gives a broader, bird's-eye view of the problem under consideration

An individual suffering from a paranoid psychosis, supported by delusions and hallucinations, and by a defensive suspiciousness, is placed in a state of sudden deprivation of his sugar In consequence of this, he goes into a profound coma with the abolition of normal defensive reflexes, the emergence of pathological reflexes, profound sweating, disturbances of the circulatory and respiratory functions, and after the neutralization of the hypoglycemia which is responsible for all these manifestations, he awakens with a more or less complete amnesia Or, in addition to the above, he manifests various expressive muscular activities reminiscent at times of the behavior of the decerebrated animal, at other times reaching a degree of chaotic disorganization in the form of an epileptic seizure and frequently possessing a distinct emotional coloring These

phenomena likewise succumb to a more or less complete amnesia. When subjected to a repetition of this artificially induced state a number of times, over eighty-five out of every one hundred paranoid patients who had been ill less than six months recover their normal health What has happened to produce this result?

In the first place, what effect, if any, has the repeated state of profound coma? Does it perhaps help to re-establish repressions which have broken down in the course of the development of the psychosis, inducing in the patient a struggle with ego-dystonic impulses which he can no longer master? However, if this were all, this therapy would be no different from the various forms of narcotic therapy, which likewise induce a state of unconsciousness To be sure, there are significant differences between the two types of coma The insulin coma is undoubtedly more profound and is definitely limited to a short time daily, followed by a rapid transition to complete consciousness, which, of course, is not the case in the various narcotic therapies

In the second place, what bearing, if any, have the various motor and emotional phenomena observed during the hypoglycemic state, phenomena which are, at times, at any rate, strongly reminiscent of an acting-out, a living-out, a catharsis in the psychoanalytic sense? Does the combination of coma as a possible aid to repression and of the catharsis as a living-out of repressed and rejected impulses, perhaps give us a clue here? It would seem that repeated exposure to such a combined state of repression and acting-out might well serve to clear the atmosphere so to speak, of the neurotic and psychotic state, especially, in view of the fact that these experiences of acting-out are followed by an amnesia and thus escape ego and super-ego critique with its consequent guilt and shame and depression Quite in line with this argument would be the observation that some of the recovered patients are distinctly shy of any attempt at a catamenistic reconstruction of their psychosis and their therapeutic experience, as though they intuitively recognized the virtue of letting the past be buried This is in marked contrast to other ex-patients who quite willingly go into detail about

MALIGNANT NEOPLASMS OF THE COLON

FRED W RANKIN, M D , *Lexington, Ky*

The most common organic lesion of the lower gastrointestinal tract is cancer, which ranks fourth in frequency in the entire list of malignancies, and occurs in approximately the same percentage as cancer of the stomach. About sixty-four per cent of a large series of cases which Graham and I³ studied some years ago were located in the rectum and rectosigmoid, while thirty-six per cent were found in the colon proper.

In few fields of surgery has such marked recent improvement been observed as in surgery for cancer of the colon and rectum, not only in the accomplishment of the extirpative act, but in the preparation before and care after operation. For a long time it has been recognized that advanced cases of hyperparathyroidism, complicated gastric lesions, obstruction in the urinary tract, and other debilitating and dehydrating chronic ailments, were best subjected to a period of preliminary rehabilitation and decompressive measures, but with cancers of the rectum and colon the story has been an entirely different one.

Recognizing that one of the most important fundamental principles of colonic surgery is the satisfactory preoperative decompression of this segment of the gastrointestinal tract the hospitalization of these individuals for a period of five to seven days during which time rehabilitative measures can be instituted, in addition to the decompressive regime, has established an improved type of present-day management. When it is recognized that sixty-eight per cent of all organic lesions of the bowel which require major surgical procedures are due to malignancy and that the average duration of symptoms is close to twelve months, it is equally obvious that an insidious undermining of physiologic equilibrium has taken place whether it is apparent or not, and that all measures which will restore the individual to a status where he is capable of undergoing a formidable surgical program, are desirable.

Another most interesting development

of the last decade has been the recognition of the important etiologic bearing on the histogenesis of cancer of the large bowel and rectum which polyps apparently have, i.e., the adenomatous variety of polyps which are found in such frequent numbers in the same location as carcinomas. Indeed, the coexistence of polyps and carcinomas in resected specimens is most commonplace and while proof is lacking that all of the carcinomas of the lower bowel do originate in polyps, there is small question that the hypothesis that many of them have their origin in such tumors is quite defensible. This thesis was proposed many years ago by Schmeiden, Westhaus, and others, and in recent years Dukes, Mummery, and others have supported it. My own interest in this relationship stimulated me several years ago to report thirteen cases with my colleague, FitzGibbon,² in which we could definitely demonstrate changes from benignancy to malignancy.

In a recent article by Lawrence¹ reviewing 7,000 autopsies performed at the Cook County Hospital, it was demonstrated that not only were polyps thickest in the rectum and sigmoid where carcinomas are most frequently found, but that the incidence of polyps found to be malignant was 3.6 per cent, while an additional incidence of 11.4 per cent of the cancers were found associated with polyps in their immediate vicinity, making a total malignancy incidence of 15.06 per cent. The incidence of polyps in this entire series of postmortem examinations was found to be 3.3 per cent, while in the rectum alone the malignancy incidence was 26.6%.

If further proof of the relationship of cancer and polyps is needed one has only to review the literature of familial adenomatosis, which is a well-known clinical entity in which death from cancer is definitely proved to be around 50%.

Diagnosis

Unfortunately, the early symptoms of organic lesions of the colon and rectum are due to secondary changes and are

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 29, 1936*

knowledge of the individual, not only as regards his vegetative and neuromuscular peculiarities, but also as regards his personal reactions is necessary. The therapy promises, therefore, to yield its best results in the hands of well-trained psychiatrists.

CANCER SITUATION "FAR FROM ALARMING"

How the people of the United States are attacking one of the country's major health problems, involving the death of 135,000 Americans annually, was portrayed before a distinguished gathering of foreign savants attending the Second International Congress of Scientific and Social Campaign Against Cancer, which convened in September in Brussels.

Before this distinguished body of scientists representing many countries and races, some facts were presented which at first glance seemed to stamp the cancer situation here as a particularly gloomy one. An American speaker, Dr. Louis I. Dublin, of the Metropolitan Life Insurance Company, and a leading authority on public health problems, declared that at least half a million persons in this country are afflicted with some form of cancer and that, among white residents, out of initial groups of 100 at birth, nine males and twelve females will eventually die from cancer, if present conditions continue. But, in his summary of the entire situation, Dr. Dublin made the optimistic statement that the cancer situation in the United States is far from alarming.

Dr. Dublin limited himself in the main to a discussion of cancer mortality. He based his facts largely upon the mortality experience of the insurance company, explaining that, for the past quarter of a century, the most comprehensive statistics on cancer in this country have been available from the experience of the Metropolitan's Industrial policyholders. He described cancer as a major public health problem, and said that it ranks second in this country in the list of causes of death, while twenty-five years ago it was only in seventh place.

"This change in position," Dr. Dublin explained, however, "is due primarily to a decline in the death rates of the other diseases."

"The death rate from cancer in the last 25 years," Dr. Dublin said, "rose 144 per cent, from 75.8 per 100,000 in 1911, to 86.7 per 100,000 in 1935. It is important, however, to point out that practically all the recorded increase in cancer occurred among males, among females the mortality from cancer declined slightly during this period."

Despite its recorded mortality increases, Dr. Dublin paradoxically questioned whether or not cancer has shown an actual increase as a cause of death. "If one were guided only by the recorded figures for cancer, as a whole," he said, "one would be led to believe that the death rate from this disease has increased during the last twenty-five years. More careful analysis, however, is necessary, and when such analysis is made, it leads to a very different conclusion."

More cancers are recognized now than formerly, due, Dr. Dublin explained, to improved diagnostic technique. Another factor is that, owing to the aging of the population, more and more persons are surviving to the ages where the incidence of cancer is greatest. When these factors are evaluated it becomes apparent that they account for much of the increase which the crude death rate shows.

"Indeed," Dr. Dublin continued, "we may say that the cancer situation in the United States is far from alarming. A number of forms of cancer are already showing declining trends. This is particularly true of those sites which are accessible and, therefore, more readily diagnosed. Throughout the country public and private facilities for the treatment of cases are increasing rapidly. Under the stimulus of the American Medical Association and of the more specialized societies of cancer experts, cancer education and research are being encouraged, and a large body of physicians is being trained to diagnose and treat cases more effectively. There are today about 200 cancer centers throughout the country which measure up to the standards of equipment and trained personnel established by the American College of Surgeons. One hospital in New York alone is now carrying over 12,000 patients on its active file. Other institutions with similar services are springing up in various parts of the country. It is encouraging to find that in the three years 1932 to 1934 the American College of Surgeons registered almost 25,000 living patients without recurring symptoms five or more years after treatment. These efforts will undoubtedly stimulate the movement for better control of cancer throughout the United States."

istic of the growth which has a tendency to encircle the lumen and thus bring about a very slow stenosis

Constipation increasingly severe and unrelieved by enemas or mild purgation is a rule in advanced cases rather than an occasional occurrence. One case out of three of left sided or rectosigmoidal cancer will present itself as a case of acute intestinal obstruction without premonitory symptoms. In the other sixty-six per cent of cases however, there will usually be some type of obstruction during the course of the disease. At times it is chronic and mild, but occasionally it progresses to a point of subacute intestinal obstruction before the individual comes for examination. Generally, the obstruction is not severe enough to demand surgical intervention and is relieved by medical measures, but occasionally the stenosis has advanced to such a point that a decompressive cecostomy or colostomy is necessary and when this does happen, the operation should be undertaken as a blind procedure for decompression only, exploration to discover the size, character, and mobility of the tumor should be deferred until some future time.

The final establishment not only of the pathological type of the organic lesion, but its location, rests in the hands of the expert radiologist. Surgeons and clinicians are fortunate in having had their radiologic colleagues advance so markedly in their technical knowledge of lesions of the large bowel within the past fifteen years.

Given a clean bowel and a cooperative patient, the radiologist can by fluoroscopy be as accurate in the diagnosis of lesions of the colon as in those of the upper gastrointestinal tract. While no physician would think of sending a patient to a radiologist for an examination of the stomach and duodenum after a full meal, it is not an uncommon incident to send an individual in for G. I. series (so called) which includes the examination of the colon, without having emptied the large bowel by purgation or enemas, or both. This results too frequently in the formation of a concrete obstruction above a stenosing colonic cancer and an acute intestinal obstruction superimposed upon a malignant condition. For this reason, if for no other, the diagnosis of organic

lesions by oral administration or opaque medium is a most hazardous procedure in addition to being very inferior to the much more sensible and practical method of administration of barium per rectum.

Operative Stage

Operation on malignant growths not acutely obstructed is enormously advantaged by a period of preliminary preparatory treatment which includes vigorous efforts at decompression along with a regime of rehabilitation. That the routine period should be lengthened to six or seven days has seemed to me to be desirable and during this time attempts at emptying the colon by irrigations and mild purgation usually will be rewarded by a complete decompression.

It is astonishing to see how frequently even subacutely obstructed colons respond to this method and at operation present none of the evidences of obstruction, save some local edema and infiltration. During the period of preliminary preparation fluids are forced to the amount of 4,000 to 5,000 c.c. daily, a diet high in calories and low in residue is insisted upon, and frequently if the patient is debilitated markedly, blood transfusions are given before operation.

In recent years, I have routinely employed blood transfusions postoperatively, but have used them before exploration only in cases which seemed definitely to need them. I am confident that this use of transfusions has aided the convalescence and recovery of many of these patients, although I am unable to explain the exact reason.

After satisfactory preparation, operation on malignant lesions of the large bowel is undertaken usually with the idea that the procedure will be accomplished in multiple stages. It is unquestionably true that many times one may do a single-stage maneuver on the right half of the colon without mortality and with a satisfactory end-result, but in a large series of cases, there is small question that multiple stage procedures will enable one to not only increase the horizon of operability, but to lower the actual hospital death rate.

In operating on the colon, I have not for years indulged in the complete operation of resection with immediate anastomosis,

not sufficiently characteristic in all cases to make the patient seek a careful examination before the disease has extended to a point of ulceration, bleeding, or obstruction, making the diagnosis obvious. Actually, the symptoms which call attention to the presence of a colonic or rectal cancer differ materially according to the location, but in general, it may be said that cancer of the right half of the colon is characterized by disturbances in physiologic equilibrium, while in the left half of the colon obstructive phenomena predominate. In the early stages of a colonic growth, changes in the bowel habit characterized by an increase in the number of stools, or by constipation, or alternating periods of diarrhea and constipation may call attention to its presence.

Constipation is a much discussed symptom of little value in rectal cancer, but is noticeable in a considerable number of cases of colonic cancer. The great difficulty in evaluating constipation and diarrhea is the patient's own attitude toward an increase or a decrease in the number of stools daily because of the very gradual change and the tendency on the part of many people, particularly middle-aged and elderly individuals, to indulge in some form of catharsis more than occasionally.

A change in the bowel habit characterized by irritability, should call for an examination if it persists for a period of a month or more, and if an examination of the stool for bright blood or occult blood, and roentgenographic examination are indulged in, usually the ulceration of the mucosa, which is small, may be demonstrated.

Second only in importance to bowel irritability, is bleeding as a symptom of organic lesions of the lower gastrointestinal tract. Once its presence is demonstrated in the stool or on the stool, no amount of effort should be spared to determine the source, for while red blood in or on the stool most frequently comes from hemorrhoids, it can come from a variety of lesions, the most important of which is cancer of the left colon or rectum.

Adenomatous polyps, diverticulitis, tuberculosis, chronic ulcerative colitis, and other lesions must be ruled out by a careful examination both proctological and roentgenographical. The presence of

occult blood in the stool is of less significance diagnostically. While it may come from cancer of the right colon, it usually indicates a lesion higher in the gastrointestinal tract such as small bowel tumor or peptic ulcer or even peptic ulcer of Meckel's diverticulum.

The very fact that too many patients with cancer of the colon are operated upon under the guise of gall-bladder disease or chronic appendicitis without having had the benefit of an x-ray either of the biliary passages or large bowel, is evidence of an unwarranted carelessness toward lesions of the lower gastrointestinal tract. With the very satisfactory diagnostic evidences of both gall-bladder and colonic lesions available, it seems scarcely possible that ten per cent of cases of right colonic cancer should be explored without an adequate diagnosis, yet such is the case.

The anemia which is so constant a picture in at least one-third of the cancers of the right colon appears without loss of blood although occult blood may be demonstrated in the stool. It may progress to a point where the hemoglobin estimate is as low as twenty-five or thirty per cent and the red cell count as low as two to two and one-half million. Occasionally this picture on first examination is confused with primary anemia, but can easily be differentiated from the latter by a study of the blood picture, or x-ray of the colon.

Attention is called to a third group of tumors which are satisfactory of prognosis and which account for about ten per cent of cancers of the colon, namely, the accidentally discovered tumors in the line of any segment of the large bowel. Palpation of a mass in the region of the cecum, transverse colon, or sigmoid in a thin individual undergoing a routine physical examination, or found by the individual himself or herself, is not an uncommon history in cancer of the colon.

In the left half of the colon the symptoms are entirely obstructive and this is due largely to (1) the character of the bowel itself which is not muscular, less elastic, and smaller in diameter than its fellow of the right half, (2) the fecal current which is formed and hard in contradistinction to the liquid stream of the right side, (3) the pathological character-

tree, particularly in elderly, devitalized individuals who have to be operated upon under local anesthesia, exteriorization is most satisfactory

The mortality following this operation however, is considerably higher than is usually believed, due largely I think, to its application to cases where some other operation should be selected. In 183 cases which I reported some years ago there was a mortality of 9.6 per cent which is a greater hospital casualty list than such an operation should carry.

The other choice of operation for the left colon is a decompression (usually cecostomy), and a subsequent resection. At this second stage one has the opportunity of selecting either an immediate anastomosis or doing an obstructive resection. It has seemed to me quite a satisfactory plan to do an obstructive resection here subsequent to the cecostomy, and it is very little more difficult to close the two colostomies than to close one.

Prognosis

Prognosis, the operability curve, and hospital mortality rate are so closely woven together that influences which reduce the latter and extend the operability rate affect favorably the ultimate outcome. That the prognosis from a statistical study of a large series of cases shows a satisfactory increase in five-year cures following radical surgery, is indisputable.

Of the many factors which influence the outlook following removal of malignancies of the large bowel, the most important in my judgment, is the intrinsic activity of the cancer cell as measured by Broders' classification of malignancy. Table I which represents a study of the outcome in 453 cases of cancer of the colon and 300 cases of cancer of the rectum reported by Olson and myself offers some interesting conclusions.

TABLE I.—GRADING OF MALIGNANCY IN RELATION TO POSTOPERATIVE LENGTH OF LIFE

	Grade 1	Grade 2	Grade 3	Grade 4
RIGHT COLON				
Incidence	16%	53%	21%	10%
Five year cures	68%	60%	48%	37%
LEFT COLON				
Incidence	13%	67%	16%	4%
Five year cures	63%	51%	30%	18%
RELATION OF GRADE TO FIVE YEAR CURES				
Five year cures	66%	56%	39%	28%

Fortunately, as demonstrated in Table I, most cancers of the colon fall into the lower grades (1 and 2) where metastasis is slower, glandular and hepatic involvement correspondingly lower, and in consequence, the result more favorable following successful removal. One also notes that there is a difference in prognosis between the right and the left halves of the colon. Just why this should be is not quite clear, but the right colon does offer a distinctly better prognosis than its fellow of the opposite side, regardless of the grade of the growth under consideration.

Five-year cures of extirpated cancers which show two out of three of Grade 1, better than one out of two of Grade 2, and gradually down to one out of four of Grade 4 survivals, indicate a hopeful prognosis.

Mortality statistics have been greatly reduced over the last two decades by increasing the safety factors mentioned above, in addition to other influences. Table II shows the operability rate and the mortality rate for cancer of the colon and rectum in my service in four recent years.

TABLE II

	Operability	Mortality
1930	57.5%	10.9%
1931	56%	9.1%
1932	55%	11.8%
1935	76%	10%

A mortality rate of ten per cent with a high operability curve should be considered satisfactory. Occasionally one does have a series of cases, either right or left colon resections, in which this rate will be improved. For instance, in my series of obstructive resections of the colon I have done seventy-one resections with six deaths, a mortality of 8.4 per cent. However, in the first series of twenty-three cases I did there was only one death—a mortality of 4.3 per cent. Graham and I reported² sixty-seven cases of aseptic anastomosis and resection for the right colon in which there were four deaths, a mortality of 5.9 per cent.

One is inclined to insist however, that the mortality rate not be reduced at the expense of the operability curve. An operability of less than fifty per cent is too low and in the hands of experienced surgeons it will be found that the average

either lateral or end-to-end except for some occasional definite reason under exceptional circumstances. It must be admitted that such a procedure can be safely done in selected cases, but as a routine method of approach, the graded maneuver has a far wider field of usefulness.

Selection of types of operation for the two halves may be divided usually into the following phases:

Right half, (1) (a) ileocolostomy (aseptic) between the terminal ileum and the middle of the transverse colon, and (b) resection at a subsequent stage, (2) ileocolostomy and resection in one stage plus a complementary ileostomy.

Left half, (1) obstructive resection, (2) (a) decompressive maneuver (cecostomy or colostomy), (b) resection by obstructive type of maneuver or resection and anastomosis, (3) exteriorization procedures (Paul-Bloch), (4) resection and immediate anastomosis with or without a complementary cecostomy.

It has seemed to me that in dealing with right colonic growths, exploration followed by an ileocolostomy of an aseptic type and a subsequent resection of the colon weeks later has been the best method. I hold no particular brief for any of the aseptic types of anastomosis save only that any clean operation is advantageous, but each surgeon should, no doubt, hold to the type of operation to which he has adapted himself. The important point which should be emphasized is that in dealing with right colonic growths the reason for a multiple stage operation is the reduction of the danger of peritonitis which easily attacks and annihilates a dessicated, dehydrated, and anemic individual, and the end-to-side anastomosis does this much more completely than the lateral. If the growth is small and freely movable and there is no evidence of pericolic infection, a one-stage resection and anastomosis may frequently be undertaken safely, but one will feel more comfortable and convalescence will be made smoother by the complementary use of an ileostomy proximal to the anastomosis line.

The principle of exteriorization applied to the right half of the colon has never seemed to me a logical one because here after the removal of the growth the liquid feces of the small bowel are difficult to control, are irritating to the abdominal

wall, and in addition, if the risk is small enough to permit exteriorization, there is small additional danger in going through with the resection and anastomosis.

In dealing with the left colon a more radical dissection of pericolic tissues and removal of mesentery can be accomplished if one does not attempt to do a complete operation in one stage and re-establish the continuity of the gastrointestinal tract.

The obstructive resection which incorporates all the satisfactory factors of an exteriorization procedure without the added danger of a primary anastomosis, is my own choice of operation provided only that the bowel obstruction has been relieved preliminary to exploration. In the last three years I have found it of distinct advantage to almost routinely supplement this obstructive resection by a cecostomy. The Witzel type of cecostomy with a Pezzar catheter keeps the bowel decompressed and makes the entire operative procedure not only a simpler one, but makes the convalescence a much more comfortable phase.

Exteriorization procedures have a very distinct field of usefulness in dealing with growths in the transverse colon and the left half. The principle of exteriorization was first introduced by Bloch, of Copenhagen, in 1892 and subsequently in the same year was modified by Paul, who did an immediate resection with decompression of the proximal colon by the introduction of a tube into the proximal loop of bowel. Mikulicz's report of a large series of these cases years later resulted in his name becoming attached to the procedure.

That there are disadvantages to an exteriorization procedure without resection and decompression is obvious for several reasons. (1) it cannot be applied to growths which occur in segments of the bowel having a short mesentery, (2) it should not be employed in large, inflammatory growths, (3) it is impractical in obese individuals, (4) any growth in which one must ligate the blood supply in order to bring the tumor out is liable to result in a gangrenous loop of bowel from which peritonitis may develop. In a segment of bowel which has a long mesentery and in which the growth may be brought out without interference to the vascular

STREPTOTHRIX AND MONILIA INFECTIONS AS CLINICAL ENTITIES

REUBEN HAYES IRISH, M D , *Troy*

In my earlier practice, I not infrequently came across these branching and budding organisms in smears from sputums examined for tubercle bacilli, as they took the carbol-fuchsin stain readily and showed considerable resistance to decolorization by the acid method

I knew they were not tubercle bacilli, and as I, like many others at that time, considered them contaminating organisms and not pathogenic, I attached little or no significance to them

Credit for the first clear description of monilia infections in the lungs and bronchi belongs probably to Castellani,¹ and the articles of Musgrave, Clegg, and Polk² published in 1908 contained an extensive bibliography on "Pulmonary Streptothricosis" Since that time the published cases and the literature on these subjects from all parts of the world have become voluminous

The only reason for reporting the cases that have come under my care or observation in the past two or three years is that the infections are still not generally recognized as definite clinical and pathological conditions with a remedy which is practically a specific if used early, before definite pathological changes have taken place in the tissues Lord³ gave an unfavorable prognosis in streptothrix infection, "because all cases of pulmonary infection in which the presence of streptothrix was satisfactorily established have died." Under "Treatment" he also stated that there is "no specific treatment" However, since that time several articles have appeared in medical journals, the prognosis is much better than it then seemed, and there is a definite drug which, if not an absolute specific, is at least of great value in the treatment of these infections

The organisms in question are thread-like, budding or branching They grow slowly in culture media, yet more readily than tubercle bacilli, take carbol-fuchsin stain readily, and usually resist decolori-

zation by weak acids and alcohol Care must be taken not to mistake them for branching tubercle bacilli from which they may be distinguished by their longer thread-like form, tendency to appear in loose clusters of numerous interlacing filaments, less resistance to acids, greater readiness with which they may be cultivated, and results of animal experimentation in special cases For it must always be borne in mind that they are frequently contaminating organisms in other infections, apparently without special pathological significance

With this introduction, I shall present the histories of the nine cases that have recently come under my personal supervision I consider these streptothrix and Monilia infections together because they have many points of similarity, such as staining and cultural peculiarities, special tendency to involvement of the respiratory tract, and general blood infection, and the same remedy seems to be of value in both infections

CASE 1 R M, male, age eleven, readmitted July 9, 1932 This patient was given a 1-500 Mantoux intradermal tuberculin test in school and gave a well-marked tuberculin reaction, after which he was sent to the tuberculosis clinic, where he came under my observation He was slightly underweight, anemic, and had enlarged cryptic tonsils and adenoids He showed changes in the tracheo-bronchial glands which, together with a tuberculin reaction, we designate as "childhood tuberculosis" I advised the removal of his tonsils and adenoids, which was done on July 1, 1932, and he was discharged from the hospital the following day apparently in good condition The next day he went to bed complaining of pain in the stomach and headache, and for two or three days had irregular attacks of hyperpyrexia, especially in the afternoon Three days later he complained of pain in the left groin and was readmitted to the hospital There was still congestion where the tonsils had been removed, and there was a yellowish membrane over both tonsillar fossae

The boy seemed very ill, so I had cultures taken from the throat as well as a blood culture. In the meantime, while waiting for

Dr Irish died April 30, 1935

Read before the Albany Pathological Society April 18, 1935

operability rate will be from sixty to sixty-five per cent. Certainly, with this figure in mind and a mortality between seven and ten per cent, the five-year cures in such a high percentage of cases is not an unexpected result.

With increasing facilities for accurate diagnosis and improved technical maneuvers which are now further supplemented by adequate preliminary preparatory measures and meticulous postoperative care, the main offensive against colonic

cancer must continue for the immediate future to be in the direction of early diagnosis before complications have supervened

THE DOCTOR AND SCHOOL ATHLETICS

It is a fine thing of course for the thousands of students in our schools to have their gyms, athletic fields, and teams of all kinds, but a Kansas medical writer remarks that if the situation be analyzed just a little more closely, one cannot fail to realize that there is more to the physical education of these students than the physical equipment, which may be purchased by the boards of education, and the physical directors. One must consider the physical development of the individual student, with regard to skeletal and muscular growth, adolescent development, and nervous and physical reserve. This analysis can only be made by someone trained in the fields of human physiology and pathology. In some of the larger institutions and school systems, this has been accomplished through the employment of part or full time school physicians.

In the smaller systems, the budget will not permit such an expenditure, therefore, the coach or physical director must rely upon that service which he is able to obtain "free gratis." Too frequently this service has been procured from individuals or cultists, desirous of making public contacts, but not capable of rendering the service required.

A few years ago, the physical director of one of the larger schools instituted routine physical examinations for all men coming under his supervision. He procured the services of two of the younger practitioners of

his community to conduct the examinations. In the course of these examinations much interesting information was obtained. There was one instance of amoebic dysentery, several hernias, occasional tachycardias or arrhythmias, etc. These students were not permitted to enter active physical training until these defects were corrected. That physical director has given his charges an immeasurable service, but that service could never have been rendered had it not been for two interested and willing M.D.'s, giving their time and service for no other remuneration than the personal and public contacts that they were able to make.

Medical men over the state should take into consideration the athletes of the forthcoming year. If possible, coaches and physical directors should be contacted, and the services of physicians should be offered to conduct physical examinations, particularly upon students entering athletic competition. Coaches should be advised that all injuries, intervening infections, and ailments should be checked to a physician, family or otherwise before active competition or further practice is permitted. Physicians should take it upon themselves to see that no athlete enters active competition, suffering from an ailment either chronic or acute, which might impair that individual's chances to carry on after school days are over.

MEDICAL RADIO BROADCASTS

The Medical Information Bureau of the New York Academy of Medicine announces the following broadcasts from Station WABC and the Columbia Broadcasting System network.

Thursday, Oct. 15, 1:30 P.M.—Speaker Dr. George Draper, Associate Professor of Clinical Medicine at Columbia University. Subject: "Relation of Human Constitution to Disease."

Thursday, Oct. 22, 1:30 P.M.—Speaker Dr. Henry S. Patterson, Medical Director at St. Luke's Hospital. Subject: "Exercise for the Middle Aged and Elderly."

Thursday, Oct. 29, 1:30 P.M.—Speaker Dr. Richard Kovacs, Clinical Professor of Physical Therapy at Polytechnic Medical School and Hospital. Subject: "Physical Treatment of Arthritis."

STREPTOTHRIX AND MONILIA INFECTIONS AS CLINICAL ENTITIES

REUBEN HAYES IRISH, M D, *Troy*

In my earlier practice, I not infrequently came across these branching and budding organisms in smears from sputums examined for tubercle bacilli, as they took the carbol-fuchsin stain readily and showed considerable resistance to decolorization by the acid method

I knew they were not tubercle bacilli, and as I, like many others at that time, considered them contaminating organisms and not pathogenic, I attached little or no significance to them

Credit for the first clear description of monilia infections in the lungs and bronchi belongs probably to Castellani,¹ and the articles of Musgrave, Clegg, and Polk² published in 1908 contained an extensive bibliography on "Pulmonary Streptothrixosis." Since that time the published cases and the literature on these subjects from all parts of the world have become voluminous

The only reason for reporting the cases that have come under my care or observation in the past two or three years is that the infections are still not generally recognized as definite clinical and pathological conditions with a remedy which is practically a specific if used early, before definite pathological changes have taken place in the tissues. Lord³ gave an unfavorable prognosis in streptothrix infection, "because all cases of pulmonary infection in which the presence of streptothrix was satisfactorily established have died." Under "Treatment" he also stated that there is "no specific treatment." However, since that time several articles have appeared in medical journals, the prognosis is much better than it then seemed, and there is a definite drug which, if not an absolute specific, is at least of great value in the treatment of these infections

The organisms in question are thread-like, budding or branching. They grow slowly in culture media, yet more readily than tubercle bacilli, take carbol-fuchsin stain readily, and usually resist decolori-

zation by weak acids and alcohol. Care must be taken not to mistake them for branching tubercle bacilli from which they may be distinguished by their longer thread-like form, tendency to appear in loose clusters of numerous interlacing filaments, less resistance to acids, greater readiness with which they may be cultivated, and results of animal experimentation in special cases. For it must always be borne in mind that they are frequently contaminating organisms in other infections, apparently without special pathological significance.

With this introduction, I shall present the histories of the nine cases that have recently come under my personal supervision. I consider these streptothrix and Monilia infections together because they have many points of similarity, such as staining and cultural peculiarities, special tendency to involvement of the respiratory tract, and general blood infection, and the same remedy seems to be of value in both infections

CASE 1 R. M., male, age eleven, readmitted July 9, 1932. This patient was given a 1-500 Mantoux intradermal tuberculin test in school and gave a well-marked tuberculin reaction, after which he was sent to the tuberculosis clinic, where he came under my observation. He was slightly underweight, anemic, and had enlarged cryptic tonsils and adenoids. He showed changes in the tracheo-bronchial glands which, together with a tuberculin reaction, we designate as "childhood tuberculosis." I advised the removal of his tonsils and adenoids, which was done on July 1, 1932, and he was discharged from the hospital the following day apparently in good condition. The next day he went to bed complaining of pain in the stomach and headache, and for two or three days had irregular attacks of hyperpyrexia, especially in the afternoon. Three days later he complained of pain in the left groin and was readmitted to the hospital. There was still congestion where the tonsils had been removed, and there was a yellowish membrane over both tonsillar fossae.

The boy seemed very ill, so I had cultures taken from the throat as well as a blood culture. In the meantime, while waiting for

Dr Irish died April 30, 1935

Read before the Albany Pathological Society April 18 1935

a growth to develop in the media, feeling that he had a general septic infection, I used mercurochrome intravenously, ten cc 05 per cent, daily for two or three days until I heard from the blood culture. The smears from the throat showed a streptothrix. A few days later the laboratory technician said she had found almost pure cultures of streptothrix in the blood, as well as mixed cultures with the streptothrix in the sputum. At that time I had had no previous personal experience with the streptothrix as a *pathological* organism. I asked what drug she had read of being used in its treatment, and she mentioned potassium iodide. I told her that I believed sodium iodide would also serve, and this being a desperate case, I decided to use it intravenously.

In the meantime, the patient had been running a typical pyemic temperature with sudden rises and sudden falls. The muscles in his left thigh became more rigid, the induration in the groin became more marked, pus formed, and the abscess opened and drained. I continued the iodide every day for two or three days, then every second day, and later syrup of hydroiodic acid by mouth.

A few days later he began to complain of a pain in the right side of his chest, cough, and expectoration, and streptothrix were found in his sputum. Later the physical signs and an x-ray indicated fluid in the pleura, and upon aspiration this was found to be pus containing the same streptothrix in almost pure culture. A surgeon was called in, who resected a portion of one of the ribs and drained the pleural cavity. The discharge was very profuse from the incision in the chest, and the wounds became infected causing a large sloughing wound which resulted in an open sinus into the pleura one to one and one-half inch in diameter, through which one could look with a flashlight and view the whole pleural cavity.

His general symptoms continued much the same for some time with irregular temperature and rapid pulse, anemia, and very marked loss of weight, until he was literally "skin and bones." He had an abscess involving the right hip joint and another at the lower end of the spine. The x-ray showed necrotic changes in bones of both hips on the lower sacrum and coccyx, and numerous sloughing areas in the skin wherever there was pressure. The pus from all of these abscesses and sloughs showed the streptothrix on laboratory examination.

The acute symptoms gradually subsided and the patient eventually recovered, but with considerable deformity, for which he was treated later at the Shriners' Orthopedic Hospital at Pittsfield, Mass. The pathogenesis of the streptothrix in this case was

never definitely established, but the clinical and laboratory evidence was so overwhelming that it left little doubt in my mind as to the nature of the infection. There seems to have been doubt, however, from a pathological standpoint, as to the classification of the organism in this particular case. I am sure it was reported on the chart at that time as a streptothrix, but proof is lacking, for the chart disappeared. I have been told that it was finally established that it belonged to the *Monilia* or mold-fungus group. I shall not attempt to discuss this question, for in this paper, dealing chiefly with the clinical aspects, diagnosis and treatment of these infections, it is not essential to settle it. The clinical picture, however, fits in better with the streptothrix infections as described in the literature.

CASE 2 W J F, age nineteen, single, was admitted to hospital Feb 17, 1933. This was a splendidly developed well-nourished young man who entered hospital in a semicomatose condition. He had been suddenly seized with severe frontal or temporal headache two or three days previously, and then it was noted that his neck became rigid and his head drawn backward. There followed extreme weakness, anorexia, gradually developing coma.

He was found in the position of extreme opisthotonos. Eye reflexes were normal, pupils equal. There was spasm of the epiglottis, irregular respiration and heart beat, muscular twitching in the right arm. Kernig's sign was present in both legs, tache cerebrale was elicited. The pharynx was red and injected. Temperature on admission was 99.2, rising a few hours later to 101.4 and varied from 101 to 103.2 for five or six days. Except for a slight amount of albumen, the urine was negative.

There was a leukocyte of 17,600 on admission, increasing in a few days to 20,000. A specimen of blood, which was sent to the New York State Laboratory, hemolized so that Wassermann and complement fixation test for tuberculosis could not be made.

Spinal fluid on admission was opaque with bright red blood. It separated on standing to a bloody sediment and a clear fluid. It was unsatisfactory for cell counts and chemical tests but Wassermann was negative. Smears (Gram stain) showed a few pus cells and fungoid growth morphologically *streptothricosis*.

Blood plates yielded a fungoid growth of the same variety as the spinal fluid. Tubercle bacilli were not found, but a few Gram positive cocci in chains and many Gram negative cocci were found.

Throat cultures yielded a staphylococcus aureus, a streptococcus, and yeast cells.

One week after admission there developed slight dullness at the base of the right lung posterior with fairly numerous small and medium moist rales, and slight pleuritic friction sound. There was cough and expectoration of a brick dust sputum, cultures of which yielded a streptothrix. X-ray showed bilateral parenchymatous thickening and marked density of the hili with no definite consolidation.

Because of waiting for growth of cultures, we were late in making the final diagnosis. Sodium iodide 15 grains was used intravenously as well as glucose. Though spinal symptoms had improved, the temperature rose after evidence of pulmonary involvement, to 106° and the patient died nine days after admission.

In this case streptothrix was found in cultures from spinal fluid, blood and sputum. The evidence convinced me that there was a general streptothrix infection with streptothrix meningitis and pulmonary involvement due to the same organism.

CASE 3 M J W, age thirty-seven. This patient had been diagnosed and treated as tuberculous. For several years he had been a patient at Gabriels' Sanatorium two or three times for short periods. When he came under my care, he was very erratic in behavior and had been a sexual neurotic since childhood. He had cough dyspnea, profuse expectoration, was always definitely overweight, and had no elevation of temperature or pulse rate at any time while under my observation. His sputum was repeatedly examined and never showed tubercle bacilli, nor could I get a history of their having ever been found in his sputum. His physical signs showed a very marked consolidation with moisture in the upper lobe of the right lung.

The things that made me suspicious that we were dealing with something other than tuberculosis were the absence of tubercle bacilli in the sputum, the fact that he never had an elevation of temperature or pulse rate, and that he remained overweight. I advised a stay of a few days in the hospital for observation. He was admitted under my care February 28, 1933. He had a discharging left ear of many years standing, and a chronic urethral discharge dating back to an old gonorrheal infection. He remained in the hospital only long enough to have specimens of sputum, ear discharge and pus from the ear and urethra obtained by massage, submitted for laboratory examination, and an x-ray of the chest taken.

A specimen of blood previously examined at the New York State Laboratory gave a negative Wassermann reaction and there was no fixation of the complement with the

antigen used in the complement fixation test for tuberculosis.

The smears and cultures from the sputum and the ear discharge showed a streptothrix and the discharge from the prostate and seminal vesicles showed a mixed infection with the staphylococcus predominating.

The x-ray report showed marked peribronchial thickening of both bronchial trees, marked parenchymal thickening of upper right lobes, and to lesser degree, of the upper left, some fleeciness of the remainder of both lungs.

Of course we could not expect to remove the changes he already had, but with the idea of stopping the process where it was, I suggested the use of sodium iodide intravenously every second day, followed by some form of iodide by mouth. After the second dose he refused intravenous treatments, and I gave him syrup of hydroiodic acid by mouth.

I understand from the family that he is in very good condition at present, is doing some work, and attending social functions connected with the church.

The case is chiefly interesting from the standpoint of diagnosis from chronic fibroid tuberculosis.

After this detailed history of two very acute cases and one chronic case of streptothrix infection of the fungus group of organisms, I shall pass to a description of Monilia infections of the yeast-like organisms.

Although I am not a pathologist, I assume, from the reports that I have received on laboratory specimens examined that the Monilia organism is not an easy one to identify, for the reports are always couched in language something like this: "A yeast-like micro-organism resembling monilia was isolated"—or this—"A yeast-like micro-organism which proved to be monilia pathogenic for a white rat was isolated."

CASE 4 W S, widow, age sixty-five living with an older sister in two rooms. Her general condition had been poor for some time, chiefly due to worry over shortage of funds and lack of regular employment. Admitted to the hospital April 5, 1934. She had not felt well for about ten days previous to that time and I had been called about three or four days before sending her to the hospital. At first she seemed to be suffering from an infection in the nose and throat. She had chilly feelings and there was definite congestion of the mucous membranes of the nose and throat with a white secretion in the follicles of the tonsils, and

a slight cough which seemed to be due to a laryngitis

On the day I sent her to the hospital, she had a severe cough with expectoration, temperature of about 101, pulse of 130, and respirations of 30. I made a clinical diagnosis at that time of bronchopneumonia and used a mixed stock vaccine in one c.c. doses every twelve to twenty-four hours, and left an order for examination of the sputum for pneumococci which were to be typed at once if present or the predominating organism reported. Due to an unexplained delay in the examination I did not get a report on the sputum until April 9. It was as follows

Sputum Reddish offensive, tenacious, opaque, mucopurulent. Pus cells and lymphocytes present. *Smears* (Gram stain) The predominating organism is one of the yeast group occurring in long rods with buds containing acid fast granules. Many of these buds have broken off and appear as individual organisms. Associated are organisms of many varieties including Gram positive cocci in pairs and small groups, a few in chain formation and a Gram negative bacillus in smaller numbers. This is a primary yeast infection and belongs in the group *Monilia*s

A subsequent examination of the sputum made at my request at the New York State Laboratory a few days later, after the patient's death, gave the following results

Cultural examination No tubercle bacilli were found. *Pneumococcus* type one was isolated. A yeast-like micro-organism resembling *Monilia* was isolated. Further tests are being made to determine its pathogenicity

It was this report in which I was especially interested, for there was some doubt in my mind that this organism was the particular pathogenic agent in this case. A few days later the State Laboratory reported that the yeast-like micro-organism isolated from the specimen of sputum, concerning which a previous report was sent, proved to be pathogenic for a white rat

The blood cultures which had been preserved in the hospital laboratory also showed a *Monilia* pathogenic for a white rat, when examined in the New York State Laboratory

When the report of the predominating organism came to me it was too late to do anything effective, although I did give her one intravenous injection of sodium iodide on April 10, five days after her admission to the hospital, and one day before she died, which was about two weeks after the first evidence of infection in her nose and throat.

CASE 5 E B, single, age seventy-four, sister of Case 4. I had treated this patient for arteriosclerosis and hypertension at in-

tervals for several years. Three or four days before her sister died, I was called to see her in a private home where she was a guest. She presented all the symptoms of an acute gastroenteritis with nausea, vomiting, a very profuse diarrhea, severe griping pains, and extreme prostration. Her temperature was about 101 and pulse about 120. I suspected the nature of the infection and two days later she was admitted to the hospital under my care. This was April 10, the day before her sister died

On admission, the gastrointestinal symptoms had somewhat improved, the pharynx and uvula were congested and there were white spots dotted over the soft palate. She had developed a cough and expectoration, and showed moderate dullness and a few fine moist rales at the posterior base of the right lung. Her sputum was the typical brick dust sputum of pneumonia, and she was in a condition of extreme prostration and stupor which gradually developed into a condition of semi-coma from which she was aroused with difficulty for food and medicine. Her arteries were thickened and blood pressure was 170/80. There was a pleuritic friction at the base of the right lung

The urine showed three plus albumen on admission and a few days later only a trace. The hemoglobin was sixty-seven per cent, red cells 3,250,000, color index 1, leukocytes 13,699, neutrophils ninety-four per cent, lymphocytes large and small three per cent, large monos one per cent, transitionals two per cent. The red cells showed marked acromia, marked anisocytosis, and moderate poikilocytosis

The laboratory reported that the sputum smears showed the predominating organism to be one of the yeast group occurring in different forms, some of them containing acid fast granules. Associated were many acid-fast Gram positive cocci scattered throughout in groups and in chains. It was the impression in the laboratory that these findings indicated primarily a yeast infection belonging in the group "*Monilia*s". Smears from the throat under Gram stain showed "a few pus cells a few Gram positive cocci scattered throughout, culture yields *staphylococcus aureus* and *streptococcus*"

On the strength of this report and because of the sister's case, I began using intravenous injections of sodium iodide fifteen grains daily. In spite of subpectoral injections of saline solution, heart stimulation, and intravenous sodium iodide, this patient seemed to be steadily losing ground.

At that time certain obvious questions formed in my mind regarding these infec-

tions, to which I could give no satisfactory answer, but after intensive reading on the subject, and an investigation of the cases made by the New York State Laboratory at my request, I believed I could answer some, at least, of these questions. The New York State Laboratory was very much interested in the subject, and sent someone to the hospital to investigate. Specimens were carefully examined in the State Laboratory. Complete reports of their findings were sent back for hospital records, and copies were sent to me.

Previous to that time the pathogenesis of these organisms had never been proven in that particular hospital. Not that these infections had not already been proven in the literature to have been pathogenic in reported cases, but since I had a larger number of cases in the course of two years than would ordinarily come under the care of one man, I wanted to prove certain things for my own satisfaction in this group of cases, and to add our observations to those already recorded.

Blood cultures taken soon after admission to the hospital showed no growth after six days incubation. When the laboratory representative arrived, this patient was practically in a condition of coma from which she could be aroused only with great difficulty. Her temperature was running from about 99 to 103.4 at the highest, pulse 100 to 138 at the highest, and respirations from thirty to fifty. I had used subpectoral saline infusions, intravenous glucose solutions, digitalis and caffeine, and continued the sodium iodide solution in daily doses of fifteen grains intravenously.

After a sufficient time for the cultures to grow out and for experimentation on animals with the cultures, we received reports in about the following order. Cultures were obtained from the hospital laboratory in the case of this patient's sister who had died a few days previously, these results I have already reported. The findings received from the New York State Laboratory were as follows:

Sputum. No tubercle bacilli were found with the Ziehl-Neelsen stain. **Cultural examination.** A yeast-like micro-organism, which proved to be a monilia pathogenic for a white rat, was isolated. A mouse, inoculated with some of the sputum, showed many lesions due to staphylococcus when autopsied. Six days later blood cultures taken at that time showed Monilia. **Stools.** Soft mass, greenish large shreds of mucous. **Smears (Gram stain).** Predominating organism is a fungus (morphological monilia). **Blood culture.** Yields Monilia. Many Monilia were isolated from the specimen of feces received on April 16. These micro-organisms proved to be pathogenic for a white rat.

This patient slowly and steadily improved. The sodium iodide was discontinued in the veins after a few days and syrup of hydroiodic acid was substituted by mouth in teaspoonful doses. She never showed symptoms of iodism during her treatment and left the hospital, none the worse for her experience, about six weeks from the date of admission, despite her advanced age of seventy-four and her general condition poor on admission.

It must be added that we did not meet with great success in trying to ferret out the source of the infection in these cases. This last case, starting as a gastroenteritis, was suggestive of a food or drink infection, although its onset some time after the sister's first symptoms suggested also a contact infection through eating and drinking utensils or air inhalation.

CASE 6 S S, age twenty-nine, housewife. This patient's mother had died of tuberculosis, and an uncle who lives with her had had a severe cough for some months. She herself had had no serious previous illness and her menstruation was regular and painless.

Her present illness began about five weeks previous to examination with what she called a very bad cold starting on the first day of her menstruation. Since onset she had very severe spasmodic cough with blood-streaked sputum at times. She had no chill or night sweats, no loss of weight, no dyspnea, and appetite was good.

She was found to be slightly above average weight, with a P.M. temperature of ninety-nine and pulse of seventy-six. There was a slight congestion in the region of the ethmoids and the dental hygiene was poor with four or five teeth carious.

Examination of the lungs showed *Right lung*. Slight dullness to second rib with fairly numerous fine moist rales on cough and on breathing. *Left lung*. Slight dullness and a few fine rales on coughing and breathing above and below the left clavicle.

X-ray showed on the right a fine dotted appearance throughout the whole lung including the apex and a thickened hilus. On the left, the hilus was thickened and there was increased density in the apex. In the first, second, and third interspaces there was the same dotted appearance seen on the right. In addition, in the inner half of the second interspace was a large opaque node, irregular in outline.

The sputum examination revealed no tubercle bacilli, but a yeast-like organism was found. Cultures of the sputum showed this organism to resemble Monilia, and, two weeks later it was reported that this organism "proved to be pathogenic for white rats."

a slight cough which seemed to be due to a laryngitis

On the day I sent her to the hospital, she had a severe cough with expectoration, temperature of about 101, pulse of 130, and respirations of 30. I made a clinical diagnosis at that time of bronchopneumonia and used a mixed stock vaccine in one c.c. doses every twelve to twenty-four hours, and left an order for examination of the sputum for pneumococci which were to be typed at once if present or the predominating organism reported. Due to an unexplained delay in the examination I did not get a report on the sputum until April 9. It was as follows

Sputum Reddish offensive, tenacious, opaque, mucopurulent. Pus cells and lymphocytes present. *Smears* (Gram stain) The predominating organism is one of the yeast group occurring in long rods with buds containing acid fast granules. Many of these buds have broken off and appear as individual organisms. Associated are organisms of many varieties including Gram positive cocci in pairs and small groups, a few in chain formation and a Gram negative bacillus in smaller numbers. This is a primary yeast infection and belongs in the group *Monilia*.

A subsequent examination of the sputum made at my request at the New York State Laboratory a few days later, after the patient's death, gave the following results

Cultural examination No tubercle bacilli were found. *Pneumococcus* type one was isolated. A yeast-like micro-organism resembling *Monilia* was isolated. Further tests are being made to determine its pathogenicity.

It was this report in which I was especially interested, for there was some doubt in my mind that this organism was the particular pathogenic agent in this case. A few days later the State Laboratory reported that the yeast-like micro-organism isolated from the specimen of sputum, concerning which a previous report was sent, proved to be pathogenic for a white rat.

The blood cultures which had been preserved in the hospital laboratory also showed a *Monilia* pathogenic for a white rat, when examined in the New York State Laboratory.

When the report of the predominating organism came to me it was too late to do anything effective, although I did give her one intravenous injection of sodium iodide on April 10, five days after her admission to the hospital, and one day before she died, which was about two weeks after the first evidence of infection in her nose and throat.

CASE 5. E. B., single, age seventy-four, sister of Case 4. I had treated this patient for arteriosclerosis and hypertension at in-

tervals for several years. Three or four days before her sister died, I was called to see her in a private home where she was a guest. She presented all the symptoms of an acute gastroenteritis with nausea, vomiting, a very profuse diarrhea, severe griping pains, and extreme prostration. Her temperature was about 101 and pulse about 120. I suspected the nature of the infection and two days later she was admitted to the hospital under my care. This was April 10, the day before her sister died.

On admission, the gastrointestinal symptoms had somewhat improved, the pharynx and uvula were congested and there were white spots dotted over the soft palate. She had developed a cough and expectoration, and showed moderate dullness and a few fine moist rales at the posterior base of the right lung. Her sputum was the typical brick dust sputum of pneumonia, and she was in a condition of extreme prostration and stupor which gradually developed into a condition of semi-coma from which she was aroused with difficulty for food and medicine. Her arteries were thickened and blood pressure was 170/80. There was a pleuritic friction at the base of the right lung.

The urine showed three plus albumen on admission and a few days later only a trace. The hemoglobin was sixty-seven per cent, red cells 3,250,000, color index 1, leukocytes 13,699, neutrophils ninety-four per cent, lymphocytes large and small three per cent, large monos one per cent, transitionals two per cent. The red cells showed marked acromia, marked anisocytosis, and moderate poikilocytosis.

The laboratory reported that the sputum smears showed the predominating organism to be one of the yeast group occurring in different forms, some of them containing acid fast granules. Associated were many acid-fast Gram positive cocci scattered throughout in groups and in chains. It was the impression in the laboratory that these findings indicated primarily a yeast infection belonging in the group "*Monilia*." Smears from the throat under Gram stain showed "a few pus cells, a few Gram positive cocci scattered throughout, culture yields *staphylococcus aureus* and *streptococcus*."

On the strength of this report and because of the sister's case, I began using intravenous injections of sodium iodide fifteen grains daily. In spite of subpectoral injections of saline solution, heart stimulation, and intravenous sodium iodide, this patient seemed to be steadily losing ground.

At that time certain obvious questions formed in my mind regarding these infec-

perimentation, therefore in acute pulmonary infections our chief reliance in diagnosis must be upon finding these organisms predominating in the smears from the sputum

In subacute or chronic infections, diagnosis should be based upon cultural findings and animal experimentation

In this connection the experiments of Bast, Hazard, and Foley⁴ of Boston, published with histories of three cases and an extensive bibliography, are worthy of note. They prepared an antigen for intradermal test in diagnosis, and prepared and used a vaccine in the treatment of pulmonary Moniliasis. This is a very interesting experiment and may be of definite service in both diagnosis and treatment

These infections may involve not only bronchi, lungs and pleura, but also joints, the gastrointestinal tract, meninges of the spinal canal, or the general blood stream. They show a marked preference for the respiratory tract, every case which I have reported showing some involvement there. There is also a marked tendency to general septic or blood stream infection, over forty per cent of the cases reported above giving a positive blood culture. These cases have convinced us that the primary infection in the large majority of cases takes place through the respiratory tract and is acquired by inhalation, although primary infection may take place in operative or other wounds, or through the gastrointestinal tract

Streptothrix infections seem to show a greater tendency to pus and abscess formation than the Monilia infection

I think there is no doubt that iodide in some form is almost, if not quite, a specific drug in the treatment of these infections. Sodium iodide, by preference, should be given intravenously in the very acute cases, or where there is general septic infection, and sodium or potassium iodide or syrup of hydriodic acid by mouth in subacute or chronic infections. Whenever possible the patient should first be tested for susceptibility to the iodide treatment

In general, I believe that the procedure in treatment of these cases is to make a probable diagnosis, based upon the predominating organism in the smears, and to start treatment, if necessary, before the diagnosis is confirmed by cultures and animal experimentation. There is certainly nothing to be lost and much to be gained by this method

In conclusion, I believe that where these organisms are definitely found as the predominating organisms in smears and cultures, they should be given the same consideration as one would give the streptococcus pneumococcus or "Vincent's" organisms under like conditions

DOUBTFUL CLINICAL LABORATORIES

Physicians who patronize unapproved clinical laboratories do a good turn neither to themselves nor their patients, observes the *New York Medical Week*. While some of the laboratories that have not sought recognition may be irreproachable in standards and practices, for the most part failure to obtain certification indicates an inability or unwillingness to meet the prescribed requirements

Aside from the question of technical performance, there are other important points at issue. Clinical pathology is an essential specialty of medicine and should be practiced only by qualified physicians, aided when necessary by competent technicians working under medical supervision. The ethical principles governing this specialty diverge at no point from those governing the rest of healing. There is no more justifica-

tion for improper advertising and secret rebates by clinical laboratories than by practitioners in any other branch of medicine

Appropriate standards for the laboratory sciences have been fixed by the A. M. A. and the American Association of Clinical Pathologists as well as the Medical Society of the County of New York. None of these organizations has the power to enforce its requirements save by voluntary co-operation, so that the maintenance of proper conditions is entirely dependent on the individual practitioner. Support of certified laboratories helps to keep control of an essential medical specialty in the hands of the profession. Patronage of unapproved laboratories undermines the authority of organized medicine and weakens the ethical safeguards against low scientific standards and unfair competitive practices

My diagnosis had been pulmonary Moniliasis. Treatment had been advised of sodium iodide from one to fifteen grains t.i.d. and glycerophosphates. The attending physician later reported that this patient's recovery was rapid, uneventful, and apparently complete.

CASE 7 Italian, age fifty-seven, baker coming in constant contact with flour dust. This patient was sent to me for diagnosis in an endeavor to secure a pension from the government. Apparently it was thought that he had developed tuberculosis while in service as a baker in the army for twenty-three months.

His chief complaints were hoarseness, huskiness of voice, and dyspnea on exertion. He was definitely overweight and had no elevation of temperature or increase in pulse rate. He had well-marked chronic catarrhal pharyngitis and laryngitis. The bases of his lungs posteriorly showed a moderate number of medium moist rales on breathing and cough. There was tenderness over this area. X-ray revealed marked peribronchial thickening in both lungs, radiating in all directions from the hilus ending in a moderately coarse mottling in the lower half of both lungs.

The complement fixation test for tuberculosis on the blood was negative. There was no Wassermann test. Tubercle bacilli were not found in the sputum, but the predominating organism was a yeast-like micro-organism resembling *Monilia*.

The diagnosis was pneumoconiosis, chronic pharyngitis, and laryngitis due to inhalation of flour dust in his trade as a baker, possible yeast infection of the *Monilia* group.

CASE 8 R. S., age thirty-six, manager of a grocery. This patient was seen in consultation Feb. 28, 1935 with a history of a severe attack of hemoptysis while on a hunting trip in Nov. 1934. He was said to have lost about one pint of blood. Following this he had morning cough with expectoration of 1½-2 ounces which was streaked for a few days. There were night sweats for the first three weeks. No sputum examination was made at the time. Since that time, his appetite had been poor, there had been moderate loss of weight, but without particular symptoms or disturbance of bowel function.

On examination he appeared anemic and underweight. The chest was long and narrow. There was moderate dullness and moisture at the apex of the right lung, but the rales were more numerous in the region of the middle lobe below the third rib, where approaching the axilla there was dullness which extended around to the spine. There were also a few fine moist rales on breathing

and cough in the upper left lobe near the sternum.

No tubercle bacilli were found in the smears examined at the city laboratory. Examination of a second specimen at the New York State Laboratory showed no tubercle bacilli in smears or cultures, but a yeast-like micro-organism resembling *Monilia* was found in the sputum cultures. This proved pathogenic when injected into a white rat.

The x-rays showed as follows: *Right*—General medium coarse mottling throughout the lung, most marked in the central portion. A few small dot-like points throughout but no definite beading along the bronchi as is frequently seen in tuberculosis. Two small nodes of marked density in the hilus. A small irregular annular shadow in the region of the inner third of the first rib. *Left*—Hilus thickened with large irregular nodes of moderate density. Some rather coarse mottling in the upper half of the lung. The apices do not appear to be involved. The right diaphragm is nearly a straight line and the cardiophrenic angle is very obtuse. *Left* negative.

A diagnosis was made of pulmonary Moniliasis, and treatment was advised of sodium iodide intravenously for two or three days, to be followed by the same by mouth.

The attending physician told me that this patient quickly showed marked improvement. I believe from my experience with other cases that his recovery will be complete.

CASE 9 L. T., age thirty-two. This patient was examined at the Tuberculosis Clinic on Feb. 1, 1935 as a possible tuberculosis contact. He was slightly overweight without elevation of temperature or increase of pulse rate. He had impaired resonance on the right side suprascapular.

The x-ray showed as follows: *Right*—Fine mottling throughout the whole lung extending well out toward the periphery. Hilus thickened and nodular. *Left*—Hilus definitely thickened. Bronchial markings similar to right though mottling is less dense. Diaphragm and angles normal.

No tubercle bacilli were found in the sputum. The predominating organism was *Monilia* of the yeast group which was proven at the New York State Laboratory to be pathogenic for a white rat.

Summary

Streptothrix and *Monilia* infections are frequently definite clinical and pathological entities.

Cultures of these organisms grow slowly, and it takes time for animal ex-

eight instances. Four of these were cases of traumatic cataract, two of which were further complicated by the presence of intraocular foreign bodies. In two patients there was an iris prolapse due to an old injury, and in one a contusion had caused an iridodialysis.

Postoperative sympathetic ophthalmia may occur in spite of any prophylactic

as Coppez⁷ maintains that if three days have elapsed, interference courts the danger of sympathetic inflammation. As a rule it is best handled by abscission of their iris and covering with a conjunctival flap, thus avoiding the danger that cauterization presents even when a flap is used.¹⁷ Cauterization was done in two clinically diagnosed cases which I have collected and both operators felt it may have been the reason for the involvement of the fellow eye.

DeGross¹³ has called attention to the fact that repeated operations add to the danger of the occurrence of sympathetic ophthalmia. More than one operation had been performed in ten of the cases in this series. The second intervention consisted

TABLE II—STATISTICS OF SYMPATHETIC OPHTHALMIA DUE TO INTRAOCULAR OPERATIONS

measures one may take.^{17 10 20} But the adoption of safe and proper surgical procedures should greatly reduce the hazard, for if there is no undue postoperative uveitis in the operated eye there will probably be no sympathetic inflammation in its fellow. However, as ocular surgery depends so much upon the cooperation of the patient, it is not always possible to avoid an accident, either during the operation or in the early postoperative course. Such mishaps occurred in thirteen of the forty-four cases in this series. Prolapse of the iris resulted in nine instances, and in two there was also loss of a large amount of vitreous, and a gaping wound.

Iris prolapse presents a serious problem, for there is added to the danger of immediate contamination the possibility of a late infection. Generally, if it is of short duration it should be corrected immediately despite any reluctance to further traumatize a recently operated eye. However, if the defect has persisted for some time, and especially if the iris is protected, correction may be inadvisable,

of discussion in three cases, linear extraction in two, iridectomy in two, sclerotomy in two, and trephining in one case.

Of the twenty-six cases in this series resulting from cataract operations, nineteen followed combined extraction of the senile type. In ten of these there was some ontoward factor, either as to the condition of the eye before operation, or some accident occurred during the operation, or shortly afterward. Two cases followed an apparently uncomplicated extraction, in which the early postoperative course was uneventful. There had been nothing in the preoperative condition of the patients to indicate that any complication might re-

SYMPATHETIC OPHTHALMIA FOLLOWING INTRAOCULAR OPERATIONS

HAROLD H JOY, M D, F A C S, *Syracuse*

While sympathetic ophthalmia is an infrequent complication of intraocular surgery, it occurs sufficiently often and is serious enough a disease to warrant the interest of ophthalmologists

Although the older statistics are often misleading due to the inclusion of other types of uveitis, postoperative sympathetic inflammation probably occurs less frequently now than formerly, due to improved technic and asepsis^{1 2 3} Many authors have collected statistics on the incidence following cataract extractions, but the literature is rather barren regarding the percentage of occurrence after other intraocular operations Theobald,⁴ in making an exhaustive study of the records of the Illinois Eye and Ear Infirmary over a period of twenty years, found three proved cases in 10,366 intraocular operations It occurred twice in 7,444 cataract extractions (0.027 per cent) and once in 2,922 other intraocular operations (0.03 per cent) Table I shows the frequency following cataract operations as found by various authors While there is some variation in incidence (0 to 2 per cent) the composite table shows that only thirteen cases occurred in over 15,000 cataract operations (0.084 per cent) This means that sympathetic ophthalmia resulted only once in nearly 1,200 cataract extractions This infrequency is further demonstrated by the scarcity of cases reported in the literature Thus, Truc and Dejean⁵ were able to collect only thirty-three cases, Hambresin⁷ eleven cases, while Puscariu² states there are in all thirty-seven published cases of sympathetic ophthalmia following cataract extraction

Of 436 cases of sympathetic ophthalmia collected by various authors ninety-one (20.9 per cent) were attributed to intraocular operations (Table II) The figures vary from a minimum of ten per cent to a maximum of forty per cent In 311 of the cases, comparison in frequency is made between those following cataract

extractions (10.3 per cent) and those following other intraocular operations (6.4 per cent)

The rarity of sympathetic inflammation after intraocular operations is only relative, for it is also infrequent after perforating injuries It is one of the two undisputed exciting causes of this disease and probably accounts for at least twenty per cent of the cases Paradoxically, while sympathetic ophthalmia infrequently follows intraocular operations, at the same time intraocular operations are a frequent cause of sympathetic ophthalmia

Of forty-four confirmed cases which I have collected for this study, twenty-six were attributed to cataract operations, seventeen followed operations on the iris, and one resulted from excision of the anterior segment of the globe¹² (Table III)

Any operation involving the anterior uvea, no matter how slight, may result in sympathetic ophthalmia As the presence of inflammatory or degenerative changes¹⁸ possibly increases the hazard, senile cataract and glaucoma may be of some importance as predisposing causes Either one or the other of these two conditions is present bilaterally in the majority of patients who develop postoperative sympathetic ophthalmia, for they are the most common reasons for intraocular surgery This is demonstrated in the present series in which 77.7 per cent of the cases followed operation for either senile cataract or glaucoma Furthermore, one can scarcely conceive of an intraocular operation that does not involve an inflamed or diseased eye, and there are no exceptions in this series In fifteen cases an additional predisposing factor was reported One patient was highly myopic, and in another a melanosis of the choroid was discovered upon histologic examination While in two patients attacks of iridocyclitis had caused the formation of posterior synechiae The predisposing factor was the result of trauma in

*Read at the Annual Meeting of the Medical Society of the State of New York,

of discussion in three cases, linear extraction in two, iridectomy in two, sclerotomy in two, and trephining in one case.

Of the twenty-six cases in this series resulting from cataract operations, nineteen followed combined extraction of the senile type. In ten of these there was some ontoward factor, either as to the condition of the eye before operation, or some accident occurred during the operation, or shortly afterward. Two cases followed an apparently uncomplicated extraction, in which the early postoperative course was uneventful. There had been nothing in the preoperative condition of the patients to indicate that any complication might re-

sult. A moderate amount of cortex remained after extraction, but there was no iris inclusion, and in neither case was the reaction marked. But about the seventh and sixteenth day respectively, an iridocyclitis developed, which progressively increased in severity and eventually resulted in sympathetic ophthalmia of the fellow eye. H. Gifford described a similar case as the worst he had ever seen, and considered the possibility that the remaining cortex may be a contributing factor in the production of sympathetic ophthalmia. Our present concept of the allergic properties of the lens indicates that this may not have been an unreasonable assumption. In any event sympathetic inflammation seems to occur rarely after intracapsular operations. Apparently all of the nineteen cases in this series followed extractions in which a capsulotomy had been done.

Operations for congenital cataract rarely cause sympathetic inflammation. Of the three cases in this series two followed dissections, and one a linear extraction. All were characterized by severe reaction in the operated eye, and in two patients a linear extraction was later necessary to remove cortex. This resulted in loss of vitreous and prolapse of the iris in one instance.

If a traumatic cataract is due to a perforating wound it may be questionable whether the resulting sympathetic involvement is attributable to the extraction of the cataract or to the original injury. In three of the four cases in this series there had been a perforation and in two of these an intraocular foreign body was present at the time of the extraction. The interval between injury and operation ranged from two weeks to six years, and in only one patient in whom the interval was six years, was the eye inflamed at the time of extraction. A prolapse of the iris occurred in two patients. It was the result of the injury in one case, while in the other it was due to misbehavior during the operation.

The exciting cause in cases following operations on the iris is usually some form of glaucoma operation. With the exception of one which followed an iridodialysis repair operation, this was true in all of the seventeen confirmed cases in the present series. It seems rather strange

that such cases appear so infrequently in the literature, for most of the different operations which have been devised to relieve intraocular tension, permanently expose the uvea to infection,²¹ while in the inclusion operations there is the added hazard of the iris incarceration.

Although the idea of deliberate incarceration of the iris is contrary to good surgical procedure, it has become increasingly popular in recent years because of its efficacy in reducing intraocular tension. The presence of five cases in this series attributed to this type of operation indicates that it is not without danger. In the only instance in which a complication was reported, a large subconjunctival prolapse of iris and ciliary body had been absceded sometime after an iridenclesis.

Although sympathetic ophthalmia admittedly occurs infrequently after trephining, the extreme rarity of cases reported in the literature¹⁶ seems rather extraordinary, for intraocular infection is an ever present possibility. It may occur during the operation or at any later time while the fistula is still patent. Though late infections are more often of a purulent nature, even this is not proof against the development of sympathetic ophthalmia. None of the three cases in this series occurred as the result of a delayed infection. The exact exciting cause is somewhat open to questions for a second operation had been done in each case. The second intervention consisted of a sclerotomy, an iridectomy, and a trephining.

Sympathetic inflammation does not often follow iridectomy,²¹ for as a rule the operative trauma is not marked, prolapse of the iris is infrequent, and a keratome incision heals promptly and securely. But the presence of seven cases in this small series indicates that it is not rare. In two of the cases the iridectomy was followed by iris prolapse, and in one a melanosarcoma of the choroid was found after enucleation. In two patients, there was definitely no complication. In one an iritis appeared on the sixteenth day and was followed eight days later by hypopyon. While in the other patient a low grade iridocyclitis developed one month after operation without apparent cause.

Of the forty-four cases of postoperative sympathetic ophthalmia in this series

some definite preoperative pathological process was present in the operated eye in fifteen instances. An accident occurred during the operation, or shortly afterward in thirteen. While in ten patients more than one operation had been performed before the other eye became involved. In five of the patients more than one of the above complications occurred. The records of thirteen cases were too incomplete to determine the presence of any untoward factors. There are only six cases in which the histories showed an absence of some such extenuating condition. In three cases following cataract extraction and in two following iridectomy, and in one due to iridenclesia no untoward factor could be determined. There was an apparent absence of foci of infection and intercurrent disease. No

definite predisposing pathological process was found in the exciting eye before operation, and no accident occurred during the operation or in convalescence.

Too little is known of the pathogenesis of sympathetic ophthalmia to properly evaluate the importance of such predisposing factors. Statistics are not available to show their incidence in intraocular operations, or as to what percentage of these cases result in sympathetic inflammation. Although there is probably a tendency to unduly emphasize a complication if sympathetic ophthalmia results, the comparatively few cases reported in which no untoward factors occur, indicate that postoperative sympathetic inflammation is quite infrequent in their absence.

Discussion

DR. HARRY M. WEED, Buffalo—Dr. Joy has done a good job in bringing the entire subject of sympathetic ophthalmia up to date and presents the results of painstaking and valuable study.

In the summary, Dr. Joy states that of the forty-four verified cases, seventeen followed operations upon the iris, and he also states that any operation on the anterior part of the uveal tract may lead to a sympathetic inflammation. This statement gives me an opportunity to discuss one angle of this subject about which very little has been said thus far, and that is the method of removal of certain types of intraocular foreign bodies. I wish here to report a case from which I believe we may be justified in drawing some rather definite conclusions.

In December 1922, a newsboy, thirteen years of age was using a hammer and chisel to cut the string binding his Sunday morning bunch of papers. A small splinter of steel $2\frac{1}{2}$ millimeters long flew up and struck his right eye perforating the cornea to such an extent that the greater part of the foreign body projected into the anterior chamber, hanging down toward

the lower angle. An attempt to remove this foreign body with an electromagnet through the wound of entrance was unsuccessful, and the foreign body soon dropped back into the anterior chamber becoming lodged on the lower part of the iris. A keratome incision was made at the lower limbus and a hand magnet was used with well-controlled current, and the foreign body removed through the limbal incision, a small iris prolapse occurred. The prolapsed iris was replaced immediately, apparently completely. The eye was kept under eserine for two days, at the end of which time the pupil was still not quite round and it seemed evident that a few fibers of the iris must be attached to the corneal wound at the limbus. The eye made a slow recovery and at the end of a month vision was normal and the eye, though for the most part white, would flush easily under manipulation, reading or exposure.

Five weeks after injury the eye became more acutely inflamed and KPs appeared, with a definite iridocyclitis. The boy was hospitalized and physical examination failed to reveal any sign of local or general infection except possibly in the tonsils which were moderately hypertrophied. These were removed.

A few days later the second eye became in-

flammed, and both eyes then went through a period of several weeks of iridocyclitis. Medical treatment was given consisting principally of foreign protein injections and large doses of salicylates.

The inflammation gradually subsided and at the end of six months the eyes were clear with vision 20/30 each, and he has had no recurrence since that time. Of course, no laboratory confirmation of the diagnosis of sympathetic ophthalmia was made inasmuch as both eyes recovered, but from the history of injury and the subsequent development of iridocyclitis, I believe we must accept the diagnosis in this case.

The point I particularly wish to make is in relation to relatively small intraocular foreign bodies that lie within the eyeball back of the anterior segment. A large number of these are not over two or three millimeters in greatest diameter, and correspond in a general way to the type of foreign body in the case which I have just described. There are two schools of belief or practice relative to the removal of these foreign bodies with the electromagnet. The older method, consists of drawing the foreign body forward into the anterior chamber, after which the problem becomes practically identical with that in my case, and the danger of iris involvement must always be considered. The other method, posterior route, consists in extracting the foreign body through an incision made in the sclera

somewhere back of the ciliary body. The principal objection to this latter method is the danger of detachment of the retina, and some ophthalmologists have very decided opinions on this subject. I recall having even heard one competent ophthalmologist make the statement that extraction of a foreign body through the posterior route constituted malpractice.

While the danger of detachment of the retina at the site of operation must be given consideration, I believe that if an incision two or three millimeters long is made in the sclera, starting five millimeters back of the limbus, we escape the ciliary body and the incision is through that portion of the retina which is firmly attached to the underlying uveal tract, and in this area detachment is extremely unlikely. But, granting that even a very occasional case of retinal detachment might occur, I am sure that with our present methods and results in surgical treatment of detachment of the retina, even this remote though possible danger is to be preferred to the possible danger of sympathetic inflammation from extraction by the anterior route.

I wish to recommend this posterior route method except in those few cases where removal of the foreign body anteriorly and probably through the wound of entrance, is the obvious method of choice.

'SPEAK UP' AT SOCIETY MEETINGS

Now that the season of society meetings is getting under way, it may be timely to pass along a word of advice from our good neighbor, the *Pennsylvania Medical Journal*. Remember, it says, that the assemblage in a room wants to hear, this is why they attend, and all speakers should regulate their voices that those present may have no difficulty in hearing. To travel the distance many do to attend the annual meeting to listen to certain papers and not to be able to hear the speaker is disheartening. There is no excuse for poor articulation.

There are some men who speak in public in a low tone, who normally have weak voices, who do not bear in mind that they are addressing an audience, and hence, never seem to realize the necessity for raising their voices.

There is the individual who invariably

looks at the floor when speaking and, to add to the difficulty of transmitting the voice, walks to and fro.

We beseech the attention of the members to this very important detail. We would urge all speakers to stand firmly on their feet, keep their heads raised, and speak sufficiently loud that the person farthest away in the audience may hear. This is imperative.

If members are unable to hear a speaker, they should have no hesitancy to arise to a point of order and request the speaker to speak more loudly. To call out "louder" from the audience is not always met with response.

Section officers should be alert in this matter, sense the situation, and request a speaker to raise his voice. It will greatly enhance the value of the meetings.

PRESENT STATUS OF THE SURGICAL TREATMENT OF RETINAL DETACHMENTS

MARK J. SCHOENBERG, M D *New York City*

Introduction

The revival of the interest in the treatment of retinal detachments took place about seven years ago when Gonin reported on his results at the Amsterdam International Congress of Ophthalmology. The fundamental idea underlying the Gonin method as well as all its various modifications is that a reattachment of the retina is possible only when one succeeds in producing an inflammatory reaction in that area of the choroid which underlies the tear or tears of the retina. This idea has been adopted by a great majority of ophthalmologists and the results seem to speak in its favor.

Operative Methods and Their Trend

I Gonin's thermocautery method is built on three pillars (1) the discovery of the tear in the retina and its exact localization*, (2) the introduction of a cherry-red hot tip of a thermocautery through an incision of the sclera, choroid, and retina at the exact spot, corresponding to the retinal tear, (3) the proper after-treatment. (Figs 1 and 2)

The main disadvantages of this operation are that (1) the exact localization of the tear is difficult and the majority of eye surgeons fail in this respect in a large number of cases (2) The heat of the thermocautery is liable to burn too large an area of the choroid, retina, and vitreous, and to produce damage and traction scars which vitiate the final outcome of the operation.

II The Gust chemical cautery method (Fig 3) consists of

1 Performing in the sclera a ring of trephine openings surrounding the place where the retinal tear or tears are assumed to be located,

2 Applying a chemical caustic, potassium hydrate, to the exposed small areas of the choroid and neutralizing the surplus of the

* The details of the localization of the tear and of the operative technic have been given in previous papers¹

caustic by a half per cent solution of acetic acid

The advantage of this method is that there is no need of extremely accurate localization of the tear

The disadvantages, however, are several

A The length of the operation (2—3 hours),

B The grave damage it sometimes causes to the sclera, choroid, retina, and vitreous,

C The impossibility of controlling the amount of cauterization desired and the size of the area cauterized,

I have seen adhesions and scar tissue formed between the eyeball and the tissues surrounding it, causing disturbances of motility and even complete immobilization of the eye.

In conjunction with this method, Lindner has developed an important modification consisting of an injection of a minimum amount of caustic between the sclera and choroid. He reported some good results. The future will show how satisfactory this delicate and hazardous method can be.

III The diathermic coagulation method consists of the application of a carefully measured high frequency current either on the surface of the sclera by the aid of a small spherical electrode or directly to the choroid, by puncturing the sclera with various types of needle pointed electrodes. This method has been developed by Larsson, Weve, and Safar (Figs 4, 5, 6, 7)

The fundamentals are the same as in Gonin's method

1 Localization of the tear—which, however, does not present the same difficulties as in Gonin's. It is sufficient to know in which sector the retinal defect is and how far back from the limbus it is,

2 Proper performance of the operation,
3 Proper after treatment

The pyrometric circuit (Figs 8, 9) consists of two wires of different metals (copper and constantan), soldered together at their ends. The wires are completely insulated except for these junctions. The cold solder is immersed in an ice bottle (0° centigrade) while the hot solder constitutes the diathermic (pyro-

metric) electrode. The copper wire is connected to the pyrometer, which is a galvanometer calibrated to read in degrees centigrade. The pyrometer records the difference in temperature between the two soldered junctions, and since the cold junction is always 0°C centigrade, the temperature of the hot junction can be read off directly.

The diathermic electrode remains cold during the passage of current, but the tissues traversed by the current are heated. If the electrode gets hot, it is only because it is in contact with the heated tissues. Consequently, the electrode can serve at the same time as a thermometer.

Fig 5 Method of pulling eye in position to expose the upper temporal quadrant of the scleral surface, in a case in which the tear of the retina was in the x o'clock meridian, fifteen mm behind the limbus of the cornea.

One of the terminals of the high frequency generator is connected to the copper wire leading to the active electrode. The other terminal is connected to the indifferent electrode in the usual manner.

The electrode is applied to the sclera with the current shut off. Then the current is opened and steadily increased until the pyrometer registers 80°C . It should take thirty seconds for this point to be reached, as this is the time required for a uniform heating of the sclera and choroid. The electrode is prevented from slipping by a short pin projecting from its center, which however is not long enough to perforate the sclera.

IV The electrolysis method, suggested by Vehhoef in 1916 has been recently revived by Vogt. It consists of numerous punctures with a very fine, sharp, and firm steel needle of the wall of the eyeball in the region of the retinal tear, right through the sclera, choroid, and retina. The cathode electrode (a fine needle) is

attached to a machine developing a very weak galvanic current ($\frac{1}{2}$ —1 milliamperes) The anode is applied on the surface of the eyeball or any other part of the body The point of the needle develops gas bubbles in the vitreous Each application lasts not more than one second Ophthalmoscopy localizes the relation of the bubble to the tear and thus informs the surgeon whether the punctures are made in the right place It is too early to decide as to the efficacy of this method

V The *Shahan thermophore* has been suggested to be used as a means of producing coagulating areas in the choroid

Fig 6 Various types of electrodes for diathermy

of eyes with retinal detachments I have had no personal experience with this method, but I doubt whether it will work out well The sclera is a tough, leathery, heat-resisting tissue To obtain a coagulation area in the choroid, one has to apply a considerable amount of heat to the outer surface of the sclera and thus would be sufficient to burn and damage it too much But, time will tell

VI Bietti of Italy has recommended the use of a mixture of carbon dioxide with acetone, applied on the sclera with the aid of a specially constructed syringe The effect of this application is to produce an inflammatory reaction in the choroid

Author's Personal Technic

After having tried for several years the various methods enumerated above, I came to the conclusion that so far the simplest and safest is the diathermic method I shall mention only the most essential features of the method as I have performed it during the past three years

Step 1 The patient should have a good restful sleep the night preceding the operation The bowels should be thoroughly cleansed by a high enema and a sedative of the barbitol group administered two hours before the operation A subconjunctival and retrobulbar injection, using one c.c. of one per cent novocain for each, are sufficient to produce the desired anesthesia for at least

Fig 7 Retractors of monel metal used by the author Can be fashioned and cut according to need during the operation

Fig 8 Coppez pyrometer circuit

Fig 9 Coppez handle and electrodes

1½ hours Use butyn, one per cent solution, as drops

Step 2 A speculum is introduced. Parallel with the limbus corneae and at a distance of ten mm from it, the conjunctiva is incised. A suture is introduced underneath the tendons of the two recti muscles between which is located the operative field. With the aid of these sutures and a sharp double hook retractor, the eyeball can be pulled in a position most advantageous for the operator. The bulbar conjunctiva is undermined and the Tenon capsule freed from the episcleral tissue as far back as it is deemed necessary. Then, the speculum is removed and small, flat, very slightly moist sponges, not larger than a postage stamp, are introduced deep into the wound, between the Tenon capsule and the sclera. This and a few drops of adrenaline hydrochloride solution (1/1000) instilled on the sponges secure a dry clean scleral surface. Once this is obtained, two specially designed retractors are introduced underneath the Tenon capsule to provide the largest possible space necessary for the careful examination of the exposed surface of the eyeball. This examination consists of three procedures

a *Inspection* as to the existence of staphylococci, thinned out areas, thickenings, discolorations, vascularized patches,

b *Palpation* with the finger or with a probe as to the consistency of the sclera and tissues underneath,

c. *Transillumination*, which is made by the aid of the ophthalmoscope minus its lenses containing head, the light source being applied on the surface of the cornea in such a manner as to illuminate the interior of the eye. The sclera becomes illuminated like a Japanese lantern. The presence of a tumor is then easily perceived as a well-delimited black blotch (Fig 7)

Step 3 The application of the diathermic current. My experience is entirely limited to the Liebel-Flarsheim apparatus which has two dials one for regulating the amount of current delivered and the other, which provides the type of current desired. One can use the coagulating or the so-called "Retinal Detachment" current which is a mixture of coagulating and cutting current. The advantage of this type of current is that it contains enough of cutting qualities to make it easier for the puncturing needles to penetrate the sclera. My own procedure is as follows. Having decided in which sector or sectors (upper nasal, upper temporal, lower nasal, lower temporal) the operative area is located, I proceed first by applying surface diathermy. The electrode I use has a small sphere of 1½ mm. in diameter, the coagulating current is switched on and the power control is set between twenty and twenty-five (Fig 6)

All being set, the electrode is applied on the scleral surface and the foot switch releases the current. The electrode is kept applied gently on the sclera until the surface underneath the electrode is beginning to become gray. The foot switch is turned off and the electrode is reapplied on the adjoining place at two-three mm distance. A ring or a semicircular row of applications is made at the proper place, surrounding the tear or on a line starting from the ora serrata, running around and behind the tear area and ending again at the ora serrata on a point symmetrical and opposite the starting point. (Fig 4)

If the surface diathermy applications have been properly applied, there is no rupture of the sclera and no oozing of subretinal fluid. The eyeball becomes quite hard.

The next step is to use a double hook electrode (Fig 6). The power control is set at thirty to thirty-five and the "Retinal Detachment" current turned on. The double hook makes a series of punctures through the sclera, obliquely, in a row parallel and out—or inside the row of surface diathermic applications. While the subretinal fluid oozes out and the eye becomes softer, it is necessary for the power control to be stepped up to thirty-five—forty. The operative area must be sponged as dry as possible. Using as little traction or pressure on the eyeball as possible helps to prevent too much fluid from oozing out.

At the termination of the operation, rapid ophthalmoscopic examination usually reveals a number of grayish-white, round areas of coagulation of the choroid. Sometimes, when the subretinal fluid is thick and gelatinous, there is very little fluid oozing out. This occurrence does not always mean a failure.

Step 4 The wound is carefully inspected for the removal of a stray sponge, irrigated with a warm salt solution, and sutured.

Step 5 The after-treatment is simple and based on perfect rest and proper position of the head. Anything that may increase suddenly the blood pressure or intraocular pressure—coughing, sneezing, lack of general relaxation, emotional upset, tossing about, etc.—may be harmful. The proper position of the head and eyes means that the patient must lie constantly in such a way that the vitreous should press by gravity against the retina towards the underlying choroid of the operated area. This must be kept up for two weeks. To prevent any unnecessary motions, the patient has to be dissuaded, if possible, from moving the bowels for one week after the operation. After two weeks in bed the bandage is taken off and a stenopeic spectacle is to be worn for two months. Sutures are to be removed

about four weeks after the operation. The first fundus examination is deferred for one week after the surgical intervention.

Results

The percentage of successes obtained by the various methods is shown in Table I.

*In my last series of forty cases sixty per cent cures were obtained.

Complications

During the operation

- 1 Slight diffuse oozing
- 2 Burning of skin of the lids with the active electrode.
- 3 Traumatic abrasion of cornea (slipping of retractor, etc.)
- 4 Early collapse of the eyeball from loss of too much fluid

Postoperative

- 1 Exophthalmos and marked chemosis from deep hemorrhage and tenonitis
- 2 Copious secondary external hemorrhage
- 3 Herpes and ulcer of the cornea
- 4 Hemorrhage in the vitreous
- 5 Ocular hypotony or hypertension
- 6 Iritis, uveitis, iridocyclitis
- 7 Diplopia from defective reinsertion of a muscle or from adhesions and cicatrices
- 8 Massive retinal coagulation, edema, and hemorrhages, necrosis of retina
- 9 Orbital cellulitis
- 10 Cataract.

Recurrences

The appearance of the detachment at the same location takes place within three to five weeks after the operation. However, Gonin has seen four recurrences after one year—two after two years and one after three years. I have seen two recurrences after one and two years respectively.

Causes of Failures

Failure may be preventable or unavoidable. As our experience becomes richer, many of the unavoidable failures will enter the group of the preventable ones.

Preventable operative failures due to (1) Diagnostic errors (2) Technical errors (3) Postoperative treatment errors.

Unavoidable failures due to Present day ignorance of diagnostic refinements establishing operative indications and contra-indications.

Questions Difficult to Answer

Every surgeon meeting with the question "to operate or not to operate" solves it, at times, in a way he thinks later on to have been against his better judgment. Some of the questions we meet are

Question 1 Should a patient with a marked arterial hypertension be operated for a retinal detachment? A The fear of the very dreaded complication—vitreal hemorrhage—advises against it. Two of my successful cases had 190 systolic pressure.

Question 2, 3 Should one reoperate? How many times should the operation be repeated even in a case whose other eye is in good condition? A As long as there is hope that a reattachment of the retina may be obtained, one should reoperate. In one of my cases with high myopia, whose retina became reattached only after a second operation, the other eye became afflicted with the same disease one year later. The second eye could not be saved on account of a massive hemorrhage in the vitreous. If I would have insisted less on a second operation on the first eye, the patient would have lost the sight in both eyes. A As many times as necessary.

Question 4 Should hypotonic cases be left alone? A. No. Some of them respond well to treatment.

Question 5 Should cases with a retinal detachment in an eye with tuberculous chorioretinitis and phlebitis be operated on? A. One case of my own had a condition of this sort and two operations were successful in reattaching the retina.

Question 6 Is there an age limit? A. My oldest patients have been sixty-nine years of age. They went through well with the operation and after treatment.

Question 7 Should old cases of one year or more standing be operated? A. The answer depends on (a) whether the patient has one good eye, (b) how the condition and appearance of the tissues of the eyeball are.

Literature contains a few cases of reat-

tachment with recovery of some vision, even when the operation has been performed one or several years after the onset of the detachment.

What Is the Trend of the Surgical Endeavor to Cure Retinal Detachments

Judging from the evolution of the problem which took place during the past few years, I would say that the tendency is towards simplification of the method

Any of the various agents employed—thermal (heat or cold), chemical, electric—have the same effect, *producing a localized inflammatory reaction in the choroid*. The future will undoubtedly develop simpler and better ways of obtaining this result.

Discussion

DR. JOHN H. DUNNINGTON, *New York City*—Dr. Schoenberg's review of the methods used in the surgical treatment of detachment of the retina is timely because it not only shows what progress has been made but it also brings home to us how much remains unsolved. I have had no personal experience with the technic he employs but I feel confident that it is a good method. I believe that there are several technics any one of which properly followed will give favorable results. At the present time I am employing the Lacarrere electrodiaphane and find it easier to use than the Walker pins and just as satisfactory.

This electrode of Lacarrere consists of a handle covered with insulating material. At its end is the active electrode, made from a thin steel or platinum wire which can be made to slide within a thin glass tube by means of a movable piece located in the handle. The end of this glass tube is slightly bent, and beveled for adaptation to the sclera. This electrode has the advantage that the depth of penetration into the ocular membranes can be graduated, and therefore one can obtain either a localized reaction to the choroid alone without perforation, or a perforation with drainage of subretinal fluid. It may be introduced under the muscles or carried to posterior regions of the eyeball, with the tube protecting the wire. The latter is not projected until the end of the glass tube is in contact with the desired place to be treated. Moreover, even if the operative field contains fluid, cauterization may be performed if the end of the glass tube is held pressed against the surface of the sclera.

Judging from my experience the most unfavorable sign accompanying a detachment is a profound hypotony, i.e., an intraocular tension of six or less (Schiotz). In the vast majority of these cases the results are unsatisfactory. If surface applications of diathermy will raise the intraocular tension, we may be more fortunate in this group. It hardly seems necessary to urge that tonometric readings should constitute a part of

the preliminary work up in every case of detachment.

Another bad omen is a detachment of great extensiveness. A few cases of almost complete detachment have responded to surgical treatment but our chances of success are much less in an extensive detachment. Macne and I in 1934 in an analysis of 150 cases of detachment of retina found that in ninety-seven with only one-half of the retina detached a cure was effected in 49.5 per cent, in thirty-six with approximately three-fourths of the retina detached a good result was obtained in twenty-five per cent and in twenty-one with almost complete detachment a cure was effected in only 9.5 per cent. Of course one may argue and with good reason that in an extensive detachment the intraocular tension is likely to be quite low and the vitreous degenerated but even when this is not true the mere extent of the detachment seems to have a very definite bearing upon the result.

While I agree with the author that one may succeed in curing a detachment in a person with an arterial hypertension, I look upon the presence of retinal arteriosclerosis as a most unfavorable sign and therefore guard my prognosis even more carefully.

Detachments accompanying inflammatory lesions should in my opinion be treated conservatively until the active process has subsided. I am sure Dr. Schoenberg will remember an illustrative case of this type he saw for me several years ago. This young man had a tuberculous choroiditis and detachment in his only eye which was treated conservatively from March to October 1931, before resorting to surgery. The Guist operation was done at that time with restoration of field and a central vision of 20/50, which he retains to date.

Dr. Schoenberg has intimated that with the newer methods exact localization of the hole is not so essential. This, I believe, is true because the entire detached area should be treated placing of course particular emphasis upon the region of the hole.

DR SEARLE MARLOW *Syracuse*.—This discussion is based on references to the recent literature, particularly the French Archives of Ophthalmology, as personal experience with the subject is negligible.

It does not seem desirable or profitable to inject the still unsettled debate as to the causal relationship of tears at this time. There is considerable evidence on both sides which time will not permit reviewing. It does seem worth while to consider how nature cures detachment. As Pascheff has recently pointed out¹ nature's method consists in the absorption of the subretinal fluid and the production of adhesions between the retina and choroid. Pascheff objects to the extensive mutilating operations which have been proposed by those who have never seen a spontaneous cure. His procedure consists in trephining the sclera (15 mm trephine) on either side of a

the individual operator with the expectation of approximately fifty per cent of cures. Thus, to be sure, is a conservative figure but the general truth of the statement is well-illustrated by Table I.² A second table compiled from the reports of five different operators comprising a total of 259 cases is also presented. The average of the percentage of cures is found to be 49.8 per cent. Undoubtedly the percentage of cures will rise as the cases are more carefully selected and the skill and judgment of the operator increases with experience.

I am sure Dr Schoenberg will agree that a great deal of the present status of the surgical treatment of retinal detachment and its future status, depends upon the careful preliminary examination of the case and the proper selection of cases. He has not had an opportunity to discuss the preliminary study of these cases but in the ques-

rectus muscle in the region of the detachment. The choroid is then perforated with a diathermic needle to allow the escape of fluid and produce two fistulae. The action of the muscle by compression aids the drainage. The patient is confined to bed only eight days.

In a paper in which are discussed some of the pathological processes which take place in the operative cure of detachment L. Weekers proposes a somewhat similar procedure. Too many such perforations are to be avoided—not more than six being advised. Weekers objects to the pyrometric electrode of Coppez and to other diathermic procedures because the thickness of the sclera varies considerably not only from one eye to another but also in different regions in the same eye. He believes that this variation is more easily allowed for by careful cauterization.

The procedure that Dr Schoenberg has adopted has already been suggested and used successfully by Mr J Cole Marshall. It is a combination of the surface coagulation, according to Larsson, with the micropuncture method of Weve and Safar.

So many different procedures have been advocated and are constantly being improved upon that it seems fair to conclude that the operative procedure itself has reached the stage at which one can be chosen to suit

tions he has raised, he has made an attempt to clear the problem of the proper selection of cases. The importance of preliminary study and of not being in too great a hurry to operate all cases is exemplified by the fact that spontaneous reattachment can occur. Villard has collected some nine well-studied cases. To emphasize this still further the following case is presented.

N G., an Indian, age forty-eight, was admitted to the Syracuse Memorial Hospital Oct 10 1931 with the history of pain and rapid failure of vision of his left eye of five days duration. In his past history there was nothing significant except that he admitted a G C infection in 1916. His general physical examination was negative except for a scar on his prepuce. His Wassermann was 4+.

His left eye was found to be suffering from an acute iritis with considerable vitreous exudate. Three days later he complained of failure of vision of his right eye which previously had been normal to examination. After dilating the pupil with homatropine the whole retina was observed to have a diffuse grayish color. Temporally a large ballooned area of detachment was discovered. The next day a similar detachment was made out in the left eye. Both optic disks appeared quite red but no exudates or hemorrhages were present. The patient was kept flat in bed, atropine maintained both pupils fairly well-dilated. He was given active antileptic treatment. He was very cooperative and at the end of six weeks was discharged with no evidence of detachment. There was, however,

tachment with recovery of some vision, even when the operation has been performed one or several years after the onset of the detachment.

What Is the Trend of the Surgical Endeavor to Cure Retinal Detachments

Judging from the evolution of the problem which took place during the past few years, I would say that the tendency is towards simplification of the method

Any of the various agents employed—thermal (heat or cold), chemical, electric—have the same effect, *producing a localized inflammatory reaction in the choroid*. The future will undoubtedly develop simpler and better ways of obtaining this result

Discussion

DR. JOHN H DUNNINGTON, *New York City*—Dr Schoenberg's review of the methods used in the surgical treatment of detachment of the retina is timely because it not only shows what progress has been made but it also brings home to us how much remains unsolved. I have had no personal experience with the technic he employs but I feel confident that it is a good method. I believe that there are several technics any one of which properly followed will give favorable results. At the present time I am employing the Lacarrere electrodiaphase and find it easier to use than the Walker pins and just as satisfactory.

This electrode of Lacarrere consists of a handle covered with insulating material. At its end is the active electrode, made from a thin steel or platinum wire which can be made to slide within a thin glass tube by means of a movable piece located in the handle. The end of this glass tube is slightly bent, and beveled for adaptation to the sclera. This electrode has the advantage that the depth of penetration into the ocular membranes can be graduated, and therefore one can obtain either a localized reaction to the choroid alone without perforation, or a perforation with drainage of subretinal fluid. It may be introduced under the muscles or carried to posterior regions of the eyeball, with the tube protecting the wire. The latter is not projected until the end of the glass tube is in contact with the desired place to be treated. Moreover, even if the operative field contains fluid, cauterization may be performed if the end of the glass tube is held pressed against the surface of the sclera.

Judging from my experience the most unfavorable sign accompanying a detachment is a profound hypotony, i.e., an intraocular tension of six or less (Schiotz). In the vast majority of these cases the results are unsatisfactory. If surface applications of diathermy will raise the intraocular tension, we may be more fortunate in this group. It hardly seems necessary to urge that tonometric readings should constitute a part of

the preliminary work up in every case of detachment.

Another bad omen is a detachment of great extensiveness. A few cases of almost complete detachment have responded to surgical treatment but our chances of success are much less in an extensive detachment. Macne and I in 1934 in an analysis of 150 cases of detachment of retina found that in ninety-seven with only one-half of the retina detached a cure was effected in 49.5 per cent, in thirty-six with approximately three-fourths of the retina detached a good result was obtained in twenty-five per cent and in twenty-one with almost complete detachment a cure was effected in only 9.5 per cent. Of course one may argue and with good reason that in an extensive detachment the intraocular tension is likely to be quite low and the vitreous degenerated but even when this is not true the mere extent of the detachment seems to have a very definite bearing upon the result.

While I agree with the author that one may succeed in curing a detachment in a person with an arterial hypertension, I look upon the presence of retinal arteriosclerosis as a most unfavorable sign and therefore guard my prognosis even more carefully.

Detachments accompanying inflammatory lesions should in my opinion be treated conservatively until the active process has subsided. I am sure Dr Schoenberg will remember an illustrative case of this type he saw for me several years ago. This young man had a tuberculous choroiditis and detachment in his only eye which was treated conservatively from March to October 1931, before resorting to surgery. The Gust operation was done at that time with restoration of field and a central vision of 20/50, which he retains to date.

Dr Schoenberg has intimated that with the newer methods exact localization of the hole is not so essential. This, I believe, is true because the entire detached area should be treated placing of course particular emphasis upon the region of the hole.

DR. SEARLE MARLOW, *Synopsis*.—This discussion is based on references to the recent literature, particularly the French Archives of Ophthalmology, as personal experience with the subject is negligible.

It does not seem desirable or profitable to inject the still unsettled debate as to the causal relationship of tears at this time. There is considerable evidence on both sides which time will not permit reviewing. It does seem worth while to consider how nature cures detachment. MUTUAL TRUST BETWEEN DOCTOR AND PATIENT

The patient who distrusts his physician will not and cannot tell him the whole truth and nothing but the truth, says the *Journal* of the A.M.A. The patient who subconsciously doubts his physician may censor facts at the expense of his recovery. The physician who lacks the confidence of a patient will try to fill the gaps in his knowledge with guesses and laboratory gadgets or else take refuge in a "look and a bottle." This has happened whenever government, contracts or other arrangements in the distribution of medical service have disturbed or destroyed continuous, confidential, personal relations between patient and physician. In some systems of insurance and workmen's compensation, medical associations—usually after years of struggle—have restored some sort of freedom of choice and mutual confidence. The result has always been an improvement in the service. Is it necessary to introduce systems that destroy these essential features of good medical service?

The medical profession has always held to the principle that change in medical service must have the single objective of better care for the health of those who need such service. Physicians are not interested in arguments for change based on the profits that might accrue to financial and industrial interests, on political expediency or even on their own apparent financial advantage, if the service is to suffer thereby.

Through the experience of centuries in many different forms of society the medical profession has learned that certain elements are essential to good medical service. One of these elements is mutual confidence, which springs from the freely chosen association of physician and patient. Compulsory association sows distrust.

Patients, not diseases, are the objects of medical treatment. Treatment rests on a meeting of two personalities, the patient and his physician. Successful, helpful relations must be between these two personalities and not between an institution, insurance system, laboratory or industry and a personality.

The patient who suspects that interests hostile to him may be influencing the physi-

cian will consciously or unconsciously describe his symptoms with a view to meeting the supposed or real antagonism. Modern psychiatry confirms this conclusion and emphasizes its importance. Laboratory technic has not displaced the necessity of confidence in diagnosis, nor has elaborate equipment made it unnecessary in treatment.

Free choice is an essential element in furthering medical progress. It is the most effective method yet discovered to insure the "survival of the fittest" in the medical profession. The selection is not always perfect, but it is more fair and impartial than selection influenced by financial or political considerations. Coercion of the decision distorts and corrupts the verdict of professional success. Professional progress has always rested on high standards of admission and then on free competition, within the limits of approved ethical regulations.

The individual choice may not always be wise, but a compulsory choice hampers the success of the best physician, while a free choice helps him to give the best service of which he is capable. Potential power of choice tends to hold all medical service to a high plane.

Economic compulsion of choice has the same evil effects that have always followed advertising and solicitation by the physician. In practice, compulsory choice is almost always accompanied by advertising and solicitation, and the choice is often made by some impersonal corporation or institution that is concerned more with other interests than with the health of the patient. This impersonal body selects a physician not for an individual patient but for a group.

Group selection usually involves mass treatment. This policy is being urged on the medical profession just as analogous fields are rejecting it. A generation ago crime and insanity were treated almost exclusively by mass confinement in asylums and prisons, mass education was glorified and mass treatment of poverty by alms and in poorhouses generally approved. Progress in criminology, psychiatry, education and social work has been measured largely by the extent to which individual personal relations have supplanted mass measures.

REPORT OF POISONING BY *CICUTA MACULATA*

Water Hemlock

D ROGER HAGGERTY, M D, *Arkport*, and JOHN A CONWAY, M D,
FELLOW A P H A, *Hornell*

The American Water Hemlock, "*Cicuta maculata*", and its varieties, is one of the most deadly and fatally toxic wild plants found in the United States^{1,9,10,11} or temperate climates, and is annually the cause of many deaths and poisonings, both in human beings and domestic animals

In New York State, excluding accidental poisonings from the eating of some one of the well-known deadly fungi "mushroom poison," *Cicuta* is, we believe, the most frequent and common cause of plant poisoning fatalities, especially among children

In presenting this paper, the authors feel they have little to offer that cannot be elicited from a review of the existing toxicology and medical literature. However, in reviewing and studying a considerable number of *Cicuta* case poisonings and reports, it has been noted that in nearly all instances the physician admittedly states that he was, when called to the case, unfamiliar with the plant,² its toxicology or the symptoms and treatment of the condition, a diagnosis as to the specific poison usually being made later from the history of the patient eating the root, and from the literature

The popular local name of a certain plant, unless the scientific name is known, serves poorly to identify the plant to which reference is made. For instance, *Cicuta maculata*, the variety found in New York State and, for the most part, throughout the East, is commonly and popularly known, in different sections, by names not at all related or referring in many instances to the same plant. Commonly, "*Cicuta*" may be known locally as musquash, water hemlock, wild parsnip, water parsnip, spotted hemlock, beaver poison, muskrat weed, cowbane, children's bane, death-of-man, snake-weed, and many others

The evident lack of medical and lay information regarding the toxicology of

water hemlock has moved the authors to present their studies and observations regarding this plant, as more or less of a public health problem, especially in rural sections

Cicuta is represented in the United States by at least eight species, all of which seem to be almost equally deadly. *Cicuta occidentalis* is found mostly in the Rocky Mountain region, *Bulbifera* in the middle northwest, while *Cicuta vagans* is found extensively throughout the Pacific Northwest. *Cicuta virosa* is the European variety

The plant, *Cicuta maculata*, as found growing in New York State,³ is an erect, tall, perennial, glabrous herb, three to six feet high, with purplish-lined, hollow stalks, and narrow pinnate leaves, with veins ending in the leaf notch, and with small, greenish white umbellicated flower heads. The root system consists of several tubiform, bulbous, fleshy root-clusters branching radially from a central root-stock much resembling the garden artichoke or small dahlia tubers

Cicuta poisoning usually occurs in the early spring months when the fleshy tuberous roots are eaten, particularly by children, being mistaken for the common garden or Jerusalem artichoke, which it resembles. At this time the roots may be heaved out of the ground by frost, or washed out by spring rains, and are frequently found exposed along the margins of creeks or ditches. The plant is distributed over much of New York State and is found in open grassy marshes and thinly wooded swamps, along backwaters and ditches. In two cases reported, the roots were picked up from the border of a muck-drainage ditch on celery land

The toxicity of *Cicuta* has been definitely recognized in this country since the middle of the Sixteenth century, before which time it was confused with the European spotted hemlock, "*Conium maculata*," a biennial plant not native to

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City April 28 1936*

widespread perivascular infiltration and some irregularly scattered pigmentary changes in both retinae. Vision was 6/12 with his glasses at the time of discharge. Five months later it was R 6/6, L 6/12 with correction.

If such a case were successfully operated early the good result would be attributed to the operation. It is not the intent of this

citation to do more than to urge careful study in each case and to allow a reasonable period of medical treatment before subjecting the case to surgery.

MUTUAL TRUST BETWEEN DOCTOR AND PATIENT

The patient who distrusts his physician will not and cannot tell him the whole truth and nothing but the truth, says the *Journal* of the A M A. The patient who subconsciously doubts his physician may censor facts at the expense of his recovery. The physician who lacks the confidence of a patient will try to fill the gaps in his knowledge with guesses and laboratory gadgets or else take refuge in a "look and a bottle." This has happened whenever government, contracts or other arrangements in the distribution of medical service have disturbed or destroyed continuous, confidential, personal relations between patient and physician. In some systems of insurance and workmen's compensation, medical associations—usually after years of struggle—have restored some sort of freedom of choice and mutual confidence. The result has always been an improvement in the service. Is it necessary to introduce systems that destroy these essential features of good medical service?

The medical profession has always held to the principle that change in medical service must have the single objective of better care for the health of those who need such service. Physicians are not interested in arguments for change based on the profits that might accrue to financial and industrial interests, on political expediency or even on their own apparent financial advantage, if the service is to suffer thereby.

Through the experience of centuries in many different forms of society the medical profession has learned that certain elements are essential to good medical service. One of these elements is mutual confidence, which springs from the freely chosen association of physician and patient. Compulsory association sows distrust.

Patients, not diseases, are the objects of medical treatment. Treatment rests on a meeting of two personalities, the patient and his physician. Successful, helpful relations must be between these two personalities and not between an institution, insurance system, laboratory or industry and a personality.

The patient who suspects that interests hostile to him may be influencing the physi-

cian will consciously or unconsciously describe his symptoms with a view to meeting the supposed or real antagonism. Modern psychiatry confirms this conclusion and emphasizes its importance. Laboratory technic has not displaced the necessity of confidence in diagnosis, nor has elaborate equipment made it unnecessary in treatment.

Free choice is an essential element in furthering medical progress. It is the most effective method yet discovered to insure the "survival of the fittest" in the medical profession. The selection is not always perfect, but it is more fair and impartial than selection influenced by financial or political considerations. Coercion of the decision distorts and corrupts the verdict of professional success. Professional progress has always rested on high standards of admission and then on free competition, within the limits of approved ethical regulations.

The individual choice may not always be wise, but a compulsory choice hampers the success of the best physician, while a free choice helps him to give the best service of which he is capable. Potential power of choice tends to hold all medical service to a high plane.

Economic compulsion of choice has the same evil effects that have always followed advertising and solicitation by the physician. In practice, compulsory choice is almost always accompanied by advertising and solicitation, and the choice is often made by some impersonal corporation or institution that is concerned more with other interests than with the health of the patient. This impersonal body selects a physician not for an individual patient but for a group.

Group selection usually involves mass treatment. This policy is being urged on the medical profession just as analogous fields are rejecting it. A generation ago crime and insanity were treated almost exclusively by mass confinement in asylums and prisons, mass education was glorified and mass treatment of poverty by alms and in poorhouses generally approved. Progress in criminology, psychiatry, education and social work has been measured largely by the extent to which individual personal relations have supplanted mass measures.

died April 4, 1912 Death certificate gives the cause of death as accidental poisoning from eating water hemlock. The history and description furnished by the two physicians who saw the case is typical of *Cicuta* poisoning. A portion of the root eaten was also identified as *Cicuta maculata*. The boy ate the root, which he mistook for the garden artichoke about 2 P.M. and died about three hours later, following prolonged, violent, epileptiform convulsions.

CASE 3 E. E. A., male, age sixteen, died March 23, 1929. The cause of death as given on the death certificate was accidental poisoning due to eating "*Veratrum Viride* Tubercle." Duration of illness was about four hours.

CASE 4 R. W. C., male, age sixteen, died March 24, 1929. The death certificate gives the cause of death the same as Case 3, duration of illness—twenty hours. Cases 3 and 4 were companions on a hike, ate the same roots, and were taken ill at the same time. A very indefinite and incomplete medical history and symptomatology states that the roots eaten by the boys were never definitely identified. However, the physician, now an aged retired practitioner, states the plant eaten was "wild parsnip," and that severe, early, and continuous convulsions were the principal, clinical symptoms.

Veratrum viride, white or green hellebore, "Indian Poke," is poisonous. However, it would be difficult to imagine a child being able to dig and eat the root which is large, deep-set in the ground and of a bitter, acrid taste. Convulsions would be also rare from *Veratrum* poisoning, the symptomatology of which is almost identical with *Aconite* poisoning. From the above history both boys undoubtedly died from *Cicuta* poisoning.

CASE 5 L. W. B., female, age forty-three, died April 2, 1933. Death certificate states as the cause of death acute gastritis due to eating leeks or "Indian Turnip Poisoning." The physician who treated this case has since died, so that no very accurate history from the medical aspect could be obtained. Patient was known to be an epileptic and mental defective. History from the family was to the effect that other members of the family had eaten of the same leeks without ill effect. As to the Indian turnip, nothing further could be learned. Indian turnip is not poisonous, furthermore due to the intense, burning, and acrid taste of this root, very little was likely to have been eaten. Death, if due to eating a poisonous root, was very probably due to *Cicuta maculata*.

CASE 6 E. M. B., female, age ten, died May 5, 1931. Death certificate states "from eating poison berries." Certificate was signed by coroner, who stated that the child accompanied the father into the woods where he was engaged in cutting wood. Father thought he noticed her eating berries. However, on later search, none of these berries could be located. From a clinical review of the symptoms, the coroner states that they definitely resembled those of *Cicuta* poisoning and were probably due to that plant.

In a study of a number of additional death certificates, statements were so indefinite as to the causes of death or the plant, root or berries eaten, that no positive deduction could be made as to the specific plant eaten.

Symptoms

The symptoms of *Cicuta* poison, as given in the recovered case just reported, are definitely classical and are those usually found and described in all cases of *Cicuta* poisoning.

Treatment

There is no specific treatment or known antidote for this drug. Early stomach lavage or emesis is always indicated, even if the case is seen late. Cases where free vomiting has occurred early usually react more favorably and give a more hopeful progress.

Symptoms should be combated as they arise. Supportive treatment with control of convulsions is of major importance and usually should be carried out, as in a case of strychnine poisoning.

Miller⁴ reports the use of sodium amytal intravenously with excellent results.

From our findings and study of the available death certificates and records in the New York State Department of Health, *Cicuta* as a cause of death, particularly in children is certainly more frequent than is usually supposed.

Physicians in attendance on plant poisoning cases should be more particular and definite in ascertaining the specific cause of the poisoning and sign death certificates with the proper cause of death. Further, such records, unless specific and definite, should not be accepted by the State Department without a thorough investigation.

this country, though naturalized from Europe. The latter is supposed to have been the poison "potion" administered to criminals by the early Greeks and Romans, and the drug which caused the death of Socrates.

The early appearance of intensely violent convulsions usually serves to definitely differentiate *Cicuta* from *Conium* poisoning, as they are said not to occur from the latter drug.

Case Report

H F, female, age fifteen, gave no history of illness except for the usual children's diseases.

About 5 P M on March 24, 1935, Dr D R. Haggerty was summoned by telephone, the information given, being that the child had been found unconscious. After a four mile drive, the patient was found lying quietly on a davenport in living room. Her mother stated that the girl was found unconscious on the bathroom floor, was rigid, and could not be roused, she was revived, however, in a few minutes and vomited considerably, complaining of dizziness and faintness.

While patient's mother was giving this brief history, patient had a severe convulsion with violent muscular twitchings, moderate opisthotonos, eyes rolling, pupils dilated, frothing at the mouth, moderately cyanosed, and neck very rigid. Patient was given one-sixth grain morphine and sent to hospital at once.

While waiting for the ambulance, inquiry brought out that during the afternoon, she was playing with other children near a muck field and found some roots which she and the other children thought were artichokes. Patient ate one bite of one of the roots, but because of its peculiar, bitter taste, threw the remainder away. About thirty minutes later patient felt nauseated and faint, and complained of severe abdominal cramps. Went to bathroom where she was found by her sister.

Patient was admitted to hospital at 5 45 P M, and had a severe generalized convulsion on a stretcher while being wheeled to her room. This lasted about four minutes and was followed by stupor. Vomiting continued at intervals until next afternoon. Had two more convulsions during the night but these were less severe. Muscular twitchings continued until next morning, gradually becoming less frequent and less severe. Heart rate came down in four hours to ninety and quality improved. Voided involuntarily until next morning.

The physical examination at hospital revealed a young, well-developed girl. Chest and lungs clear throughout. Breathing slow and shallow. Heart sounds weak and distant, rate 120, rhythm normal. Temperature was 99.4 F rectal.

Abdomen Recti-muscles rigid. *Extremities* moderately rigid. Marked frequent and irregular muscular twitchings, involuntary urination. Reflexes very active.

Urinalysis Sp gr 1020. No albumin. Slight trace of sugar. No casts. No crystals. Blood count normal.

Treatment

General supportive and palliative measures were used. Because of frequent vomiting, gastric lavage was not done. Patient was frequently given as much warm soda water as she would take. Morphine was given to control convulsions and to combat shock, and high hot colonic irrigations every four hours. External heat to body and pilocarpine to produce diaphoresis.

Thirty-six hours after eating root, appeared fairly well. Complained of neck being lame and sore. Some nausea still present. Recovery complete in forty-eight hours—no ill after effects.

Root eaten was identified as *Cicuta maculata* by Mr William Groesbeck, Hornell Laboratory.

Additional Death Reports

In a further investigation of plant poisonings in New York State, the following deaths, due undoubtedly to this plant, were investigated and studied.

CASE 1 H E W, male, age eleven, died on April 9, 1920, following the eating of a root of the same variety of plant that caused the poisoning in the non-fatal case just reported. In fact, the root was procured from the same section of the same field. The physician who attended the case has since died. However, the family described the symptoms, which were found to be typical of *Cicuta* poisoning.

The child ate the root about 4 P M. Convulsions began about two hours later and death occurred at 9 P M in severe convulsions. The cause of death on the death certificate is given as "eating wild parsnip." This could not possibly have been the cause of death as the wild parsnip is simply the common parsnip escaped from our gardens and is not poisonous. Moreover, the fibrous, single rootstock of parsnip, uncultivated, due to its woody formation, would be edible only by animals.

CASE 2 W R G, male, age fifteen,

Symposium: Arthritis

BLOOD CHANGES IN ARTHRITIS

RUSSELL L. CECIL, M D, *New York City*

*From the New York Hospital and the
Department of Medicine, Cornell University Medical College*

Arthritis is a term which may be applied to any inflammatory condition of the joints. It occurs in a number of different forms, depending on various etiologic agents. The diagnosis of arthritis is simple enough. It is often quite difficult however to determine the cause of the arthritis. The most important point for determination in any case of either acute or chronic arthritis is whether it is infectious or non-infectious in character. Once this point has been settled, a long step in advance will have been made in the handling of the case. Having established a diagnosis of arthritis, the physician should ask himself the following questions:

- 1 Is this an infectious arthritis?
- 2 If infectious, what is the organism?
- 3 If not an infection, what physical or chemical agent is responsible?

These differentiations are made by means of various clinical and laboratory findings. In the present discussion on arthritis I wish to limit myself to a consideration of certain changes which occur in the blood in the various forms of arthritis. It is surprising what a wide variety of reactions may take place in the blood of arthritic patients, and these reactions are of great value to the clinician in differential diagnosis.

As a guide to our discussion, let me refresh your memory with a simple classification of arthritis, a classification which is quite generally accepted now by students of this disease.

- 1 Infectious arthritis
 - A. Of known etiology, including arthritis caused by gonococcus, pneumococcus, tubercle bacillus, etc.
 - B. Of unknown etiology. The most important of this group are rheumatic fever and rheumatoid arthritis.
- 2 Degenerative arthritis, which includes various forms of osteoarthritis, such as Heberden's nodes, osteoarthritis of the hip, menopausal arthritis, etc.

- 3 Traumatic arthritis
- 4 Allergic arthritis, or serum sickness
- 5 Metabolic arthritis, the most important form of which is gout

Let us now take up in more detail these various types of arthritis, with special reference to the blood changes which may occur in each form.

Specific forms of infectious arthritis are usually secondary manifestations of a blood stream infection, the bacteremia resulting from some primary focus. In many of these cases the exciting micro-organism can be recovered not only from the joint fluid but from blood cultures as well. In many instances however the bacteremia is of a temporary character, and blood cultures may fail to yield the etiologic agent. When these specific joint infections are acute, the leukocytes are usually elevated, with an increase in the total polymorphonuclear count and in the percentage of immature cells. In the more chronic forms, such as those caused by the tubercle bacillus or the spirochete pallidum, the white count may show slight, if any, elevation, but even in chronic cases the Schilling count will usually show some shift to the left. An increase in the sedimentation rate of the red blood cells is also one of the usual findings in specific bacterial infections of the joints, and in general it may be said that the more active the infection, the higher will be the sedimentation rate.

A. Infectious arthritis of known etiology

1 Gonococcal arthritis. This is one of the commonest forms of specific infection of the joints and usually follows a gonococcal urethritis. During the acute stage the blood changes characteristic of active infection are present. The gonococcus may be recovered from the blood stream in severe cases, but in the average infection blood cultures are sterile. McEwen, Alexander, and Bunim¹ have recently reported the recovery of streptococci from the blood stream in fifteen per cent of patients with

*Read at the Annual Meeting of the Medical Society of the State of New York
New York City, April 29, 1936*

No information was at hand or available to judge the non-fatal cases of *Cicuta* poisoning, however, reports in the literature from other states usually give fairly numerous non-fatal cases in connection with the reporting of fatal cases. It has long been a saying or "grapevine report," indefinite and probably not always authentic, especially in the rural communities, that such and such a child died or was ill from eating "wild parsnips." How many of such reports are authentic we have no means of knowing.

Prevention

Education, especially of school children and others in sections where the plant is known to grow, as to the identification of the plant and its poisonous properties, both for men and domestic animals, is of the greatest importance.

Eradication. *Cicuta* should be hand-pulled, grubbed-out, and burned as soon as discovered.

Cicuta poisoning among domestic animals on farms of the middlewest and on the western cattle ranges are more or less common, so much so, that several exten-

sive studies, investigations, and reports have been made by State and Federal Agricultural Departments.

From a study of the literature, a considerable number of additional reports of poisonings have been elicited.

Anfin Egdahl,⁶ 1911, reported a case of poisoning due to eating *Cicuta maculata*, also, reported at that time forty-eight cases reviewed from the literature.

Stratton,⁷ of Denver, reported eleven cases with two deaths.

Gompertz,⁸ New Haven, reported seventeen cases in one group of boys. Though most of these were intensely ill, no fatalities occurred.

Discussion

DR. PAUL BROOKS, *Albany*—Dr Haggerty's description of the experience with *Cicuta maculata* and his mention of the possibility of its being mistaken for horseradish reminds me of one of my own experiences when I was in practice. Several members of a family developed an acute gastroenteritis as a result of eating what was supposed to be horseradish, prepared from a root which had been dug by one of the family. They were able to produce a specimen of the root and it was identified by an expert as poke root. It did not smell or taste like horseradish and it was difficult to understand how fairly intelligent people, as these were, could make such a mistake. It shows how easily such mistakes can happen.

DR S W SAYER, *Gouverneur*—About twenty years ago, I was called to see a boy six years of age who had been suddenly seized with severe convulsions.

This boy lived with his parents on the bank of the Oswegatchie River. Along side of the houses ran a small brook and on each side of this brook and extending to the river bank was a marshy area.

Careful questioning and search of the house disclosed no drugs which might have

been taken by this boy. The illness developed very suddenly, falling a short distance to the ground in a convulsion, which continued, the intervals between them were so short that the child did not become entirely conscious so that we were unable to obtain any history whatever.

Within an hour, the temperature began to rise and the child died about 2½ hours after his first symptoms, which resembled those due to strychnine poisoning symptoms.

A spinal fluid was taken and was reported to be normal. It is my opinion that this case might have well been one of the *Cicuta maculata* poisoning.

DR. JOHN A. CONWAY—Dr Brooks' and Dr Sayer's report both help to confirm our belief that the extent of poisoning by *Cicuta maculata* is much more than we have been able to discover from a study of death certificates.

I recently have been informed by Dr Fred Graves, State Veterinarian in charge of milk, that he has personally seen cattle that were undoubtedly poisoned by this plant but at the time, did not recognize the condition. Dr Graves believes that many of these instances occur in cattle poisoning where the condition is not recognized.

that non-hemolytic streptococci are of etiological importance in rheumatic fever

Clawson and his coworkers¹⁵ tested the serum of rheumatic fever patients against two strains of streptococci, both of the viridans type, and found the agglutination titers of the serums distinctly higher than controls. Keefer, Myers, and Oppel¹⁶ found positive agglutination reactions against hemolytic streptococcus in twenty-six per cent of patients with rheumatic fever. Coburn and Pauli¹⁷ found agglutination responses in the sera of patients with rheumatic fever, but because of the low titer these authors felt that too much significance should not be attached to them.

Precipitin reactions Coburn and Pauli carried out precipitation tests with the serums of rheumatic fever patients against the protein fractions of streptococcus hemolyticus. Precipitins were demonstrable in the sera of ten patients with acute rheumatic fever, and the concentration of the precipitins became more marked as the activity of the process heightened. The precipitins disappeared with subsidence, and returned during recrudescence of the disease.

Schlesinger, Signy, and Payne¹⁸ found precipitins against various chemical fractions of the hemolytic streptococcus in about one-half of their rheumatic patients. They thought that the presence of precipitins was related to complicating streptococcal infection rather than to the rheumatism itself, for many patients with typical rheumatic symptoms but without a recent history of streptococcal infection failed to develop precipitins.

Hodge and Swift¹⁹ were not able to follow any constant relationship between the severity of rheumatic symptoms and the presence of precipitins against either the carbohydrate or the nucleoprotein fractions of the hemolytic streptococcus.

McEwen, Bunim, and Alexander²⁰ carried out precipitin reactions with the C-fraction of streptococcus hemolyticus and found that in thirty-nine patients with rheumatic fever, fifty-six per cent gave positive precipitin reactions. In thirty-two per cent the reaction was strongly positive. In normal controls twenty-four per cent were positive, but only five per cent strongly so.

Antihemolysins One of the most interesting immune responses observed in rheumatic fever is the development of antihemolysins in the patient's serum. Todd²¹ first called attention to this antihemolysin which is present in the blood serum and is capable of neutralizing the hemolytic substance formed *in vitro* by the streptococcus

hemolyticus. By following hemolytic streptococcus infections Todd found that this substance increases in amount in the blood serum during the active stage of the disease. Working on the theory that rheumatic fever was caused by the hemolytic streptococcus, Todd titrated the serums of patients with rheumatic fever for antihemolysins against the hemolysin of the streptococcus. He found that patients with symptoms of active rheumatic disease had a high antihemolysin titer, and that during the period of quiescence the titer fell almost to normal.

The observations of Todd have been abundantly confirmed by Coburn and Pauli. They found that the average antistreptocolysin titer for normal serum was seventy-one "units" whereas the average titer developed in acute rheumatism was 500 units. The onset of acute rheumatism coincided with a sharp rise in the antistreptocolysin titer. Streptococcus infections of the throat without rheumatic manifestations caused little or no rise in the amount of antistreptocolysin.

Myers and Keefer²² examined the serum of thirty-three cases of rheumatic fever and found the antistreptocolysin titer was higher than that for normal individuals, and that it was about the same as with cases of proven streptococcal infections.

Blair and Hallman²³ studied the sera of eighteen patients with rheumatic fever for their content of antihemolysins. Fifteen gave readings decidedly higher than the normal. The three patients whose readings were within the normal range were inactive at the time and were in the hospital because of cardiovascular disease.

McEwen and his coworkers obtained antistreptocolysin titers which were well above normal in sixty-six per cent of fifty-one patients with rheumatic fever. These investigators found that the antistreptocolysin readings above were limited almost entirely to patients with non-streptococcal diseases or active rheumatic fever.

Resistance to fibrinolytic activity of the hemolytic streptococcus Tillett and Garner²⁴ have recently demonstrated that broth cultures of the hemolytic streptococcus will rapidly liquefy the fibrin-clot of human plasma. Cultures of other bacteria fail to exhibit this property. Tillett, Edwards and Garner²⁵ found that the blood plasma of patients convalescent from acute hemolytic streptococcal infections was highly resistant to the action of hemolytic streptococcus cultures. This observation has been confirmed by other investigators. Myers, Keefer, and Holmes²⁶ confirmed these findings and further showed that the resist-

gonococcal arthritis. In nine per cent of these the organisms were of the hemolytic type. Blood cultures from one of McEwen's patients yielded both gonococci and hemolytic streptococci.

The works of Kristjansen and others² have shown that the gonococcus complement fixation test is of real diagnostic value in gonococcal arthritis. In our clinic we have come to look upon this test as of the greatest importance, and we should be loath to make a diagnosis of gonococcal arthritis in the face of a negative complement fixation test. Keefer, Myers, and Holmes³ obtained a positive complement fixation reaction on the blood serum in eighty to eighty-six per cent of patients with gonococcal arthritis. In cases in which the reaction was negative the genital infection had usually been present for less than two weeks.

2 Infectious arthritis caused by the ordinary pyogenic cocci is usually, but not always, monarticular and is often spoken of as a surgical joint, or suppurative arthritis. As a matter of fact, many of these joints fail to progress to the stage of suppuration. The joint fluid however, even if not purulent, is usually cloudy, due to the presence of leukocytes and desquamated endothelial cells. Blood cultures are frequently positive in this form of arthritis. The organisms which may be recovered are pneumococcus, streptococcus, staphylococcus, or meningococcus. The usual leukocytic reactions are present, and the sedimentation rate is high.

3 The tubercle bacillus and the spirochete pallidum usually produce a chronic form of arthritis. The blood changes in tuberculous arthritis are not noteworthy. In syphilitic arthritis a positive Wassermann reaction will be obtained in practically one hundred per cent of the cases.

B. Infectious arthritis of unknown etiology

Rheumatic fever should still be listed as a disease of unknown etiology though the evidence in favor of a streptococcal origin is becoming more convincing every year.

One of the most striking features of rheumatic fever is the secondary anemia which nearly always develops in patients who have a prolonged attack of the disease. Both the hemoglobin and the red cell count are reduced considerably. During the febrile stage when the joints are acutely inflamed there is a leukocytosis of from 15,000 to 25,000, which slowly decreases with the diminution of symptoms. In the monocyclic form the count returns to normal after a few weeks and remains so. In the polyyclic and continuous forms a low-grade

leukocytosis may continue over a considerable period of time. Hand in hand with the leukocytosis goes an elevation in the sedimentation rate. The leukocytes and the sedimentation rate provide a fairly accurate gauge to the patient's progress, and failure to return to normal even when the fever and joint symptoms have entirely disappeared is highly suggestive of continued activity of the rheumatic process. These tests are particularly valuable in cases of rheumatic carditis where it is difficult to know just when the activity of the lesion in the heart has terminated, and may be of considerable aid in deciding when bed-rest can be terminated.

Blood cultures. For thirty years or more a lively controversy has been carried on by bacteriologists concerning the presence and significance of streptococci in the blood stream of rheumatic fever patients. Time does not permit an extensive review of this interesting subject. On the positive side are the studies of Poynton and Paine,⁴ Rose-now,⁵ Clawson,⁶ and our own investigations at Bellevue Hospital.⁷ On the negative side are the studies of Lazarus-Barlow,⁸ Nye and Seegal,⁹ Cooley,¹⁰ and Kinsella and Swift.¹¹ To make the subject still more confusing, a third group has recently appeared who recover streptococci in the blood not only in rheumatic fever but in many other conditions as well. The more important of these reports are those by Callow,¹² Wilson and Edmond,¹³ and McEwen, Alexander, and Bunim. The percentage of positive cultures reported from rheumatic patients has varied all the way from ten to sixty-five per cent, and the type of streptococcus most frequently found has been the "viridans", though indifferent and hemolytic types have also been recovered. McEwen and his coworkers recovered streptococci from the blood stream in sixty-one per cent of patients with acute tonsillitis, an interesting finding when one recalls how frequently rheumatic fever is preceded by acute infection of the tonsils.

Agglutination reactions. Nicholls and Stainsby¹⁴ carried out agglutination reactions with serums of patients with rheumatic fever against a non-hemolytic streptococcus of the viridans variety, which had been originally isolated from the blood of a patient with rheumatic fever. The agglutination test showed that the serums of most rheumatic fever patients contained considerable amounts of specific agglutinin for this strain, while control serums possessed little or no agglutinative power for this organism. In the opinion of Nicholls and Stainsby the results of these agglutination reactions furnish additional evidence

any reference to the type of arthritis under consideration. The writer, in collaboration with Nicholls and Stainsby,³³ reported the isolation of streptococci from the blood stream in 62.3 per cent of 154 cases of rheumatoid arthritis. Most of the strains recovered in this series were attenuated hemolytic streptococci. This study awakened considerable interest in the bacteriology of rheumatoid arthritis, and since its appearance a number of studies have appeared along similar lines, some confirming and some failing to confirm these observations. Space does not permit a complete review of this rather voluminous literature. The studies of Rosenow,³⁶ Gray, Fendrick, and Gowen,³⁷ Wetherby and Clawson,³⁸ and Ashworth,³⁹ confirm the findings of Cecil Nicholls, and Stainsby, whereas Nye and Wixelbaum,⁴⁰ Bernhardt and Hench,⁴¹ Dawson, Olmstead, and Boots,⁴² and Wainwright⁴³ fail to confirm our findings. Dawson, Olmstead, and Boots implied that the technic which had been employed in our blood culture studies invited contamination, and they suspected that the organisms which had been recovered by us and by other bacteriologists were contaminants from the air or the skin. More recent studies however have supported our contention that these streptococci are actually present in the blood stream. For example, McEwen and his coworkers found streptococci present in seventeen per cent of patients with rheumatoid arthritis, but they obtained a slightly higher percentage of positive streptococcal cultures in senescent nonfebrile states and in acute tonsillitis. Even normal healthy controls yielded streptococci in five per cent of the cases. McEwen believes that the streptococci are actually present in the blood stream, but questions their significance in view of the fact that they are found not infrequently in non-arthritic bloods.

Streptococcal agglutinins. One of the most interesting phenomena observed in the serum of patients with rheumatoid arthritis is the presence of streptococcal agglutinins. These agglutinins were first described by Cecil, Nicholls, and Stainsby in 1931, who showed that most of their "typical strains" of attenuated hemolytic streptococci were agglutinated by the serum of rheumatoid patients. In a series of 153 cases of rheumatoid arthritis, ninety-seven per cent showed agglutination with "typical strains" of streptococci at a dilution of 640 or higher, while in a series of fifty normal controls, the serum in every case failed to give a strong agglutination reaction. Of 102 pathological controls only two patients gave a positive reading at a dilution of

640 or higher. These investigators also observed that hemolytic streptococci from other sources such as scarlet fever and erysipelas were often agglutinable by arthritic serum. Dawson, Olmstead, and Boots confirmed the presence of these streptococcal agglutinins in the serums of patients with rheumatoid arthritis, obtaining positive readings in sixty-seven per cent of their cases. They also found that hemolytic streptococci from other sources were often agglutinated by the serum of rheumatoid patients. The presence of these agglutinins in rheumatoid serums has now been corroborated by a number of investigators, including Gray, Fendrick and Gowen, Wetherby and Clawson, Kiefer, Myers, and Oppe, Wainwright Cox, and Hill⁴⁴ and Blair and Hallman. The last mentioned authors found agglutinins in high titer in eighty-five per cent of their patients.

Nicholls and Stainsby found that in patients with advanced arthritis the agglutination titer was higher than in those with less involvement. On the other hand, they felt that the actual duration of the disease and the age of the patient had very little influence on the strength of the agglutination reaction. Their opinion is supported by the recent study of Blair and Hallman who found no relation between the agglutination titer and the age of the patient, duration of the disease, or the number of joints involved. In our experience the agglutination reaction has not run closely parallel with the sedimentation rate. However, it may be stated that as a general rule patients with a high sedimentation rate show strong agglutination reactions and vice versa. As recovery takes place the agglutinins tend to diminish and eventually to disappear, but they are not so sensitive a guide to the condition of the patient as is the sedimentation rate.

Precipitins. Dawson, Olmstead, and Jost⁴⁵ studied the precipitin content in the serums of seventy-one cases of rheumatoid arthritis. Thirty-eight gave positive or doubtful reactions with the carbohydrate and nucleoprotein fractions of streptococcus hemolyticus. In the same series of cases thirty-four of the seventy-one gave positive or doubtful agglutination reactions with the streptococcus hemolyticus. These investigators found that all sera which showed high agglutination titers gave positive precipitin reactions. They conclude that there is a close approximation in the ability of rheumatoid sera to agglutinate streptococcus hemolyticus and to precipitate the various group-specific fractions of this organism. They further concluded that these findings offered suggestive evidence in

ance to fibrinolysins of the plasma of patients with rheumatic fever is comparable to that of patients with erysipelas and other acute streptococcal infections. Similar results have recently been reported by McEwen, Bunim, and Alexander.

Summary 1 In rheumatic fever we have the blood reactions which characterize any acute or subacute infection.

2 In a certain percentage of cases (the percentage differing in different laboratories), streptococci of various types are recovered from the blood stream of rheumatic fever patients.

3 With respect to immune responses in the blood, specific streptococcal agglutinins and precipitins have been demonstrated by various observers. More recently antihemolysins against the hemolysin of the streptococcus hemolyticus have been demonstrated in the serums of rheumatic fever patients, and still more recently it has been shown that the blood plasma of patients convalescent from rheumatic fever is highly resistant to the fibrinolytic activity of hemolytic streptococcal cultures.

We have evidence therefore from various reactions in the blood that rheumatic fever is not only an infectious disease, but that in all probability it is related to streptococcal infection. Much of the evidence points toward the hemolytic streptococcus as the exciting agent, but the possibility of the non-hemolytic streptococcus being implicated can not be dismissed.

Rheumatoid Arthritis

More than one writer on rheumatic disease has pointed out the close similarity between rheumatic fever and rheumatoid arthritis. Although it does not seem likely that the two diseases are identical, there are many reasons for believing that they must be rather closely related etiologically. These diseases have many clinical features in common, and when one reviews the blood changes which occur in rheumatoid arthritis, one can not fail to be impressed with their similarity to those just described as occurring in rheumatic fever.

Changes in blood count Secondary anemia is just as common in rheumatoid arthritis as it is in rheumatic fever. Both the hemoglobin and the red cell count are often markedly reduced. The leukocyte count may show some elevation, particularly in active cases, but the counts do not run so high as they do in rheumatic fever. The percentage of immature cells is frequently elevated even in cases where the total white cell count shows no elevation. The author noted a shift to the left in nineteen of

twenty-eight cases (67.8 per cent). In some of these, the percentage of immature cells was three to four times the normal. Eaton reported an increase of the immature cells in eighty per cent of 250 patients with chronic arthritis (type of arthritis not specified). Steinbrocker and Hartung claim that in their investigations one hundred per cent of patients with rheumatoid arthritis showed an elevation in the immature cells. My personal opinion, however, is that this estimate is too high.

Sedimentation rate of the red blood cells A number of studies have appeared in the last few years on the sedimentation rate in rheumatoid arthritis. The more important have been those of Race,²⁷ Dawson, Sia, and Boots,²⁸ Kahlmeter,²⁹ and Forestier.³⁰ In the author's series of fifty-two cases the average sedimentation rate for patients with rheumatoid arthritis was three times the upper limit of normal. The sedimentation rate is not only of diagnostic value in separating arthritis of the infectious types from traumatic and degenerative forms of arthritis, but it possesses considerable value as a prognostic test. In most arthritis clinics, the sedimentation rate is determined every three to four months in order to gauge the value of the treatment employed.

Snapper and others³¹ have shown that the power of the red blood cells to settle at various rates is dependent on three factors, namely, the cell volume, plasma fibrinogen, and plasma globulin. When these three constituents are normal, the sedimentation rate can be calculated with a fair degree of accuracy. Rubinstein and Fisher,³² Hurwitz and Meyer,³³ and others have shown that there is not only a rise in the plasma globulin but a fall in plasma albumin in certain febrile diseases, especially in pneumonia. Davis³⁴ has made use of these factors in an interesting way by studying the plasma proteins in rheumatoid arthritis. He found that in rheumatoid arthritis there was a rise in the plasma globulin and a fall in the plasma albumin similar to that observed in various infectious diseases. Davis believes that his findings suggest the infectious nature of rheumatoid arthritis.

Blood cultures I have already indicated in the discussion on rheumatic fever that a sharp controversy still exists among bacteriologists as to the presence or absence of streptococci in the blood stream of rheumatic patients. A similar argument has been going on for the past ten years concerning the bacteriology of the blood in rheumatoid arthritis. Even before the last decade there had been a few reports on the finding of streptococci in the blood of patients with chronic arthritis, but without

In a series of cases which the writer investigated several years ago, thirty-one cases of osteoarthritis showed an average sedimentation rate only slightly above the normal limit. This is so regularly the case that when the sedimentation rate is high one should suspect the presence of some infectious element. Investigators are very much in agreement that the streptococcal immune reactions which have been described under rheumatic fever and rheumatoid arthritis are conspicuously absent in the hypertrophic forms. Nicholls and Stainsby studied the serums of forty-four cases of osteoarthritis. Only six of them showed any agglutinins at all, and these were all at a dilution of 1:80 or less. McEwen examined the serums of forty-six cases of osteoarthritis and found no evidence of streptococcal agglutinins in a single case. Dawson, Olmstead, and Boots obtained negative agglutinins in seven cases of osteoarthritis. McEwen and his coworkers obtained positive precipitin reactions in a few cases of osteoarthritis, but the reactions were nowhere nearly so strong as those obtained in rheumatic fever and rheumatoid arthritis. Several investigators agree that antistreptococcal and the antifibrinolysins are absent in the serums of patients with hypertrophic arthritis.

The blood chemistry of osteoarthritis is not noteworthy. A certain number of these patients will show a high blood sugar, but this finding is not unusual in any group of middle-aged patients. Bauer, Bennett, and Short have recently studied the blood chemistry in cases of hypertrophic arthritis and found no significant changes in the serum calcium or phosphorus, or in the blood sugar, urea or creatinine. Bruger and Poindexter⁴⁹ found that the plasma cholesterol was higher in hypertrophic arthritis than it was in atrophic arthritis. Hartung and his coworkers found the mean cholesterol content of the plasma to be above normal in fifty-nine cases of osteoarthritis, and felt that this finding could not be explained on the basis of either senescence or obesity.

Osteoarthritis then can be sharply differentiated from the various forms of infectious arthritis by the absence of the blood changes characteristic of infections, and of streptococcal infections in particular.

Traumatic arthritis

Traumatic arthritis is usually nothing more than a sprain, and tends to heal very rapidly unless complicated by a fracture of one of the articulating surfaces. It should be remembered however that trauma to a joint may be the predisposing factor to a genuine arthritis, which may be infectious, degenerative, or even gouty in character.

Allergic arthritis

Allergic arthritis or serum sickness is an acute condition and usually clears up spontaneously. There may be a slight leukocytosis, but this is temporary in character.

Gout

Gout is a disease of metabolism. The metabolic disturbance has to do with the oxidation and elimination of purins. The salts of uric acid accumulate in the blood, and under certain conditions are deposited in the tissue about the joint. The most constant of the blood changes in gout is an increase of uric acid in the circulating blood. The amount of uric acid in one hundred c.c. of normal blood varies between 2 and 3.5 mgs.

McClure and Pratt,⁵⁰ employing the method of Folin and Denis,⁵¹ found that in normal individuals the blood contains less than three mgs. of uric acid per one hundred c.c. In seven gouty patients the blood uric acid varied from 3.3 mgs. to 5.8 mgs. per one hundred c.c. of blood. No relation was found between the amount of uric acid and the nitrogenous substances in the blood. Hopkins and Wolf⁵² claim that the normal amount of uric acid varies from 2 to 3.5 mgs. and that in gout four to ten mgs. may be obtained. Pratt⁵³ found the uric acid was notably increased in gouty patients in the intervals as well as during the acute attacks. In Pratt's series of twenty-one cases of genuine gout, the average amount of uric acid in the blood was 3.7 mgs. per one hundred grams of blood. All students of gout admit however that in a few cases of undoubted gout the uric acid in the blood may be found within normal limits, but even in these cases when the patient is on a purin-free diet it never drops below 1.5 mgs.

Most modern chemists make use of

favor of the hypothesis that rheumatoid arthritis is associated with infection by streptococcus hemolyticus

Antihemolysins In our discussion of rheumatic fever it was noted that antihemolysins appeared in the sera of a high percentage of patients with active rheumatic fever. Investigators have naturally been curious to know if these anti-bodies were also present in the sera of rheumatoid arthritis patients. Myers and Kiefer studied the serum in thirteen cases of rheumatoid arthritis and found that the disease was not accompanied by an increase of the antistreptolysin titer of the blood serum. McEwen and his coworkers noted high readings of antistreptocolysin in the sera of only a few cases of rheumatoid arthritis. On the other hand, Blair and Hallman investigated forty-five patients with rheumatoid arthritis and found antistreptocolysin present in titers definitely above normal in one-third of the sera. Furthermore, these high titers with one exception accompanied high agglutination titers. Blair and Hallman conclude that the presence of streptococcal agglutinins and antistreptocolysins in the sera of patients with rheumatoid arthritis suggests an association of this organism with the disease.

Antifibrinolysins As noted under rheumatic fever, the fibrin clots from practically all patients with acute hemolytic streptococcus infection show increased resistance to fibrinolysis by hemolytic streptococcus cultures. Similar resistance to fibrinolytic action was observed in the fibrin clots of patients with rheumatic fever. Myers, Kiefer, and Holmes have applied this test to a number of patients with rheumatoid arthritis. The findings were similar to those in normal controls, with a few exceptions in which the clots showed high resistance to fibrinolysis. McEwen and his coworkers have reported results quite similar to those of Myers, Kiefer, and Holmes.

Just why these differences in streptococcal immune reactions should exist between rheumatic fever and rheumatoid arthritis we are unable to say at the present time. It is obvious that the discovery of these serological changes may have considerable significance as regards the etiology of both diseases. It can not be stated as yet just how much practical value such reactions have in the differential diagnosis of arthritis. In the opinion of the writer however the streptococcus agglutination reaction has distinct value in the identification of rheumatoid arthritis. Streptococcal agglutinins are present in a high percentage (approximately ninety per cent) of these patients. From the recently published studies of Co-

burn, I think it is fair to say that the antistreptocolysin reaction could be employed with value in the diagnosis of rheumatic fever. These tests are all very new and it will take time to determine their full biological significance and clinical value.

Chemical changes in the blood Patients with rheumatoid arthritis show no characteristic changes in their blood chemistry. In a certain percentage of cases the blood uric acid may be elevated but rarely to a point where one would suspect gout. Pemberton⁴⁶ and his associates claimed that the blood sugar was often elevated in rheumatoid arthritis and that these patients had a poor sugar tolerance. These observations however have been questioned by several investigators. No important changes in serum calcium or serum phosphorus, or in calcium and phosphorus metabolism were discovered by Bauer, Bennett, and Short⁴⁷ in patients with rheumatoid arthritis. Hartung and his coworkers⁴⁸ have recently shown that the mean cholesterol content of the plasma is lower than the normal in rheumatoid arthritis, and they believe that this finding supports the infectious theory of its etiology.

Summarizing the various serological reactions which occur in rheumatic fever and rheumatoid arthritis, we may say that the agglutinins and precipitins tend to parallel each other while the antistreptocolysins and the anti-fibrinolysins are roughly parallel. It is interesting to note that agglutination and precipitin reactions with the hemolytic streptococcus are strongly marked in rheumatoid arthritis but weak or absent in rheumatic fever, whereas antistreptolysins and antifibrinolysins are usually present in rheumatic fever but absent or weakly positive in rheumatoid arthritis.

Osteoarthritis

Osteoarthritis is a degenerative process akin to other phases of senility and in this respect presents a strong contrast to infectious arthritis which is inflammatory in nature. One would naturally infer that the reactions of inflammation would be absent in osteoarthritis, and such indeed proves to be the case. The leukocyte count is within normal range. Secondary anemia is rarely noted. The sedimentation rate is normal or slightly elevated. Forestier noted that in fifty-five cases of osteoarthritis sixty-two per cent showed a normal sedimentation rate and in twenty-eight per cent the rate was slightly elevated, there was only one with a rate as high as twenty mm.

USE OF HEAT IN THE CARE OF THE ARTHRITIC PATIENT

STAFFORD L. WARREN, M.D., and EMMY LEHMANN, R.N., Rochester

From the Division of Radiology, Department of Medicine of the University of Rochester School of Medicine and Dentistry and the Strong Memorial Hospital

For the past two years we have attempted to work out a practical standardized method of treatment using heat alone in a group of twenty patients hopelessly crippled with advanced infectious arthritis in a constant state of exacerbation. The patients were in varying subacute stages of the disease after bouts (months) of lowgrade fever, still suffering severe pain, swelling, and almost complete disability. These patients had been treated previously by many of the different procedures suggested for arthritis without lasting effect. All of these patients have been relieved of their acute and progressive symptoms and the majority (70%) have shown an increase in calcium deposits radiographically in their bones and at the joint surfaces.

Our routine was to have them eat a general diet plus one quart of milk per day, have them wear heavy woollens to avoid being chilled, and then give no

medication other than aspirin for pain. Heat in various forms was tried in an effort to find first the most effective and later the most economical and practical method of holding this disease in check.

It was our purpose to evaluate the effects of the hot bath routine alone (described below), prolonged local treatments with diathermy (3-8 hours a day) two or three times a week through the effected joints, and a combination of the hot bath and local diathermy treatments and hot soaks.

The etiological factor or factors in infectious arthritis are as yet unknown, but in our opinion and for reasons as yet unknown, the opportunity for recurrence of the symptoms once the disease has started is ever present in this geographic region. In other words, once an arthritic, the patient is always an arthritic—the variation being only in the quiescence or activity of the disease. With this postulate

Folin's improved method for the determination of uric acid in the blood. This method was published in the *Journal of Biological Chemistry* in March 1930.

Spondylitis

So far nothing has been said about the value of blood tests in the differential diagnosis of spondylitis. The two important types of spondylitis are the infectious form, often referred to as the Marie Struempell spine, and hypertrophic spondylitis, or osteoarthritis of the spine. The infectious form of spondylitis is often associated with rheumatoid arthritis. When it occurs alone as the so-called "poker spine" in young men, the blood will show the reactions characteristic of infection, but the streptococcal agglutination reaction is usually negative. This suggests of course that spondylitis deformans is not always referable to the streptococcus, and this would fit in with our clinical observations, for one sometimes sees this form of arthritis coming on after gonorrhea or even after typhoid fever. In osteoarthritis of the spine the blood reactions differ in no respect from those seen in hypertrophic arthritis elsewhere in the body. In other words, no noteworthy blood changes are observed.

Discussion

The five types of arthritis which are seen most frequently in clinics and private practice are gonococcal arthritis, rheumatic fever, rheumatoid arthritis, osteoarthritis, and gout. Some may raise the question as to whether gout should be included in this group, but certainly in private practice in New York city gout is a fairly common disease. We have seen from the preceding remarks that, with the exception of osteoarthritis, there are fairly reliable blood tests for each of these forms of arthritis, namely, the complement fixation test for gonorrheal arthritis, the antistreptocolysin test for rheumatic fever, the agglutination reaction for rheumatoid arthritis, and the blood uric

acid determination for gout. The least dependable of these tests is the antistreptocolysin determination in rheumatic fever. The other three tests can be considered fairly reliable and practical in their clinical application. Not nearly enough use is being made of the streptococcus agglutination reaction in the diagnosis of rheumatoid arthritis. The writer has found this test of great practical value in differential diagnosis. Nor should we lose sight of the theoretical significance of this reaction in further study of the etiology of rheumatoid arthritis. It seems fairly certain that streptococci of various types can be recovered not infrequently from the blood of patients with various acute infections and chronic constitutional disorders. In most instances they probably have little or no significance. In rheumatoid arthritis however, streptococci can frequently be recovered from the blood, and positive streptococcus agglutination and precipitation reactions can be obtained in a high percentage of patients with the disease. These findings would certainly suggest that in rheumatoid arthritis the streptococci were more than accidental or harmless travellers in the patient's blood.

Conclusions

In the commoner forms of arthritis the differential diagnosis can usually be made by careful studies of the blood. Infectious arthritis can be differentiated from the non-infectious forms by means of the leukocyte count, the Schilling hemogram, and the sedimentation rate of the red blood cells. In the differentiation of the prevalent infectious types, other blood examinations have proven useful. The more important of these are the complement fixation test for gonococcal arthritis, the streptococcal agglutination reaction for rheumatoid arthritis, and the antihemolysin test for rheumatic fever. The identification of gout can usually be achieved by determining the uric acid content of the blood.

relieved over a long period of time following a single artificial fever at 40.5° C maintained for four hours. After having had one fever treatment, three cases with mixed arthritis have gone almost three years without recurrence of symptoms. Fever therapy as a hospital procedure probably has its most effective use in stopping the acute phases of the exacerbation of symptoms even if it does not prevent later exacerbations from occurring.

In the absence of facilities for administering fever therapy, the most potent weapon is the hot bath when used as a modified fever treatment. This can be used routinely by the patient throughout the cold weather period. The arthritic process in a great many patients of the older group can be kept quiescent by this procedure when kept up regularly three times a week or occasionally as often as three times a day, or enough to relieve symptoms of acute exacerbation. The directions for this are very simple, and, when supervised by a physician, are, in the average case, devoid of danger. The two major contraindications for the use of the baths in this manner are severe myocardial insufficiency and advanced vascular disease, although a restricted use under careful supervision might be practical since the duration of the bath at best is short (15–20 minutes). Age (68 to 75 years) is no contraindication. The important features about the hot bath routine are the elevation of the mouth temperature to 101° F as measured by a thermometer and the regularity with which it is kept up for indefinite periods, especially throughout the cold part of the year. In this climate this means for about eight months. The general lack of risk from the short hot bath, its low cost and simplicity has made this bath routine very successful as a procedure in the home. In fact its effect has been just as pronounced as the single general fever therapy where the temperature is raised to 40.5° C (or 104.5° F) and maintained at this level for various periods of hours. Raising the mouth temperature above 101° F in the bath is apt to be followed by faintness, weakness, and prostration, and is not well-tolerated by the patient. The patient should be warned that this is dangerous.

With both treatments, there is an immediate subsidence of symptoms. With the general fever treatment this may last a week or ten days, following which the symptoms may recur although gradually diminishing over the following four to six weeks. In favorable cases they may disappear sometimes for months. The patient usually gains from ten to fifteen pounds in weight and feels rejuvenated.

Over the same period of time (4–6 weeks) the same gradual subsidence of symptoms occurs with the hot bath routine although the patient should expect the symptoms to recur each morning. This is alleviated somewhat by starting the day with a hot shower. The same gain in weight and the same influx of energy is noted. Herpetic lesions of the face occur with as great frequency after the hot bath routine as with the fever treatment.

Certain cases will need no further therapeutic procedures, but the patient should be kept on the hot bath routine (2–3 times a week) just the same for the rest of the cold weather, and whenever cold extremities or stiffness develop the patient should warm himself immediately by a hot soak, hot shower, bath, or any other practical method. Others following the development of an acute respiratory infection or some other unknown factor will have an exacerbation of their symptoms. If severe, this is best handled by putting the patient to bed, and continuing the hot bath routine daily until the symptoms subside. Or if the exacerbation is severe enough to necessitate its immediate cessation, the patient may be given a general fever treatment in the hospital.

If one or several joints are particularly slow in responding the application of additional heat to these joints seems to speed up the repair process. This can be applied in several ways—the most economical being the use at home of heat upon the joint for two or more periods each day of not less than one hour and preferably for two hours or more. This is accomplished most simply by using a twenty or forty watt ordinary electric light bulb at a comfortable distance from the skin over the joint (2–4 inches). The heating should be gentle and prolonged and ought not to produce an erythema.

TREATMENT OF ARTHRITIS, WITH PARTICULAR REFERENCE
TO VACCINES AND ALLERGIC REACTIONSCHARLES H. HITCHCOCK, M.D., *Syracuse*

Two years ago I presented a paper before this body upon the treatment of infectious or "rheumatoid" arthritis with hemolytic streptococcus vaccine. At that time reference was made to the state of streptococcal allergy which exists in this disease and in rheumatic fever, and certain experimental observations were described which led to the choice of the intravenous route for administration. It was pointed out that in the majority of cases, following proper surgical control of infected foci, the judicious administration of vaccine intravenously is followed by distinct amelioration of symptoms. It was emphasized that prolonged courses of treatment are necessary in order to obtain good results. In the discussion, Dr. Rawls reported a high percentage of successes in patients thus treated with vaccines selected according to certain criteria which he had evolved. Such vaccine treatment is, in effect, an attempt at lessening the degree of sensitivity which these patients exhibit toward streptococcal products—that is, a more or less successful desensitization. Reports from different parts of the country have confirmed the value of the procedure, although strains and dosages employed have varied considerably. Particularly in the matter of dosage wide discrepancies have appeared, which it is not within the scope of this paper to discuss. The fact remains, however, that successful results have been reported by both large and small dose advocates.

I should like to discuss here the failures—the unfortunate minority to whom this treatment fails to be of value, in whom, in fact, it may lead to intensification of the disease, and may even be followed by a spread to previously uninvolved joints. Such cases seldom find their way into statistical reports, except to be grouped in the column of "unimproved" and there abandoned. This does not, however, dispose of their arthritis, and many of them wander from clinic to clinic, vainly seeking relief. Possibly the man who is particularly interested in the arthritis problem is blessed with an undue

percentage of them. Not all can be helped, at present, however, with careful study some amelioration can be obtained in many.

During the past two years several such patients have been encountered, all with obstinately persisting arthritis, and all intolerant to streptococcus vaccine. In all of them, clinical sinusitis from staphylococcal infection has been found. Despite adequate treatment of the infected sinuses, no improvement has resulted, nor has there been a lessening of the intolerance to streptococci. Some have been submitted to intensive treatment with autogenous staphylococcus vaccine, but no benefit has resulted. During these attempts at therapy, considerable sensitivity to the vaccine has been observed, for an overdose will produce reactions, sometimes of several days' duration. In no case, however, have such reactions resulted in a permanent intensification of the arthritis, or in a spread of the process to fresh joints. That such patients, infected by staphylococci and sensitive to this organism and its products should also be highly allergic to hemolytic streptococci is to be fully expected from certain experimental results in laboratory animals, and is by no means an argument that the process was initiated originally by streptococci. For example:

A woman of thirty-five suffered for two years from a mild but annoying multiple arthritis which persisted in spite of removal of obvious dental and tonsillar foci. It was found that she harbored a staphylococcal infection of the right sphenoid sinus. Adequate drainage was secured and maintained, and over a period of several months she was treated with small intravenous doses of hemolytic streptococci, without improvement. In fact the only apparent effect of the vaccination was to induce reactions, increase the arthritic discomfort and increase the amount of sinus discharge. Autogenous staphylococcus vaccine was then administered for several months more, without result. It was then determined to try the effect of combining injections of staphylococcus toxoid with the vaccine. The first few treatments revealed the presence of a high degree of sensitivity to the toxoid.

This is most readily applied through the use of a flexible goose-neck type of student reading lamp with a metal shade. Such a lamp (20 watt bulb) may be put in the bed beside the patient with safety. This is much more efficient than a heating pad. Any other convenient source of heat may be utilized at the discretion of the physician.

Diathermy of one kind or another has been in use for a long time for the treatment of painful joints, but the effectiveness of such treatment is enhanced very materially by prolonging the treatment for periods of from two to eight hours, with short rest periods of five to ten minutes every two to three hours. Such treatments undertaken one to three times a week for a month will often be sufficient and are far more effective than twenty to forty minute treatments three to five times a week over the same period. The main objection is that one patient ties up a single machine for such a long time.

If the patient does not have a bath tub or electricity in the home, the problem of caring for the disease is very greatly increased, and one must then rely upon the non-specific methods of producing fever or "shock" by foreign proteins and various other types of medication.² With the use of these agents, as well as in the use of stock vaccines, the same lag of from four to six weeks seems to occur before the relief of symptoms is obtained, although in some cases, as with the hot

baths or with fever therapy, the relief is immediate and prolonged.

Conclusion

The proper use of heat (hot bath routine and local treatment) consistently and over a long period of time is very effective in the control of the symptoms of infectious arthritis. A good part of the use of this therapeutic agent can be done by the trained patient, supplemented from time to time if necessary, by additional and more intensive application of heat by the physician. Until a more specific therapeutic agent is found, this represents a simple and safe, and in general an effective type of therapy. We believe that there is no short cut to the long drawn-out use of heat in these patients. First of all, the patient should be put in the best physical condition by the removal of all foci and the relief of all other loads upon his body systems. The hazard of respiratory infection should be reduced as much as possible. He should keep warm, and never allow himself to become fatigued. Heat in the most practical form should be used without restriction for the alleviation of his symptoms. In fact, the patient must almost make his life over to conserve and supplement his normal body heat mechanisms.

Discussion

DR. K. G. HANSSON, *New York City* — The physiological action of heat is (1) increase of body temperature, (2) hyperemia, (3) increase of respiration and circulation, (4) a sedative action on the nervous system, (5) relaxation of muscles, (6) increase of cell metabolism, and (7) a change in the reaction of the body fluids from an acid to an alkaline reaction. The type of heat is of subjective value.

In rheumatoid arthritis, where we usually deal with a patient who is below par in general health, with muscular atrophy, heat can be used generally for its tonic effect, and locally for its sedative action.

In osteoarthritis, which is often accompanied by overweight, heat can be used generally for reducing, as in an electric cabinet, and also locally on the joints. In-

ternal heat in the form of diathermy, short-wave, or ultra-short-wave, are very useful. The painful fingers can be successfully treated by paraffin dips.

Specific arthritis, I believe, is where hyperpyrexia, or artificial fever treatments belong. My experience with hyperpyrexia in other forms of arthritis, has been discouraging. A series of cases of rheumatoid arthritis that I treated with hyperpyrexia, showed only temporary relief, and the sedimentation rate was not affected (*Journal of Bone and Joint Surgery*, Jan 1934).

Heat will always be a part of the management of arthritis, but it should be used with discrimination as to dosage and time, and specific instruction should be given to the patient, if the maximum benefit is to be obtained.

gunning in the fall of the year, he was given intravenously a long course of autogenous vaccine. It was quickly found that fifty-five diplococci reproduced his symptoms with great regularity, whereas forty were well-tolerated. During the winter his sinus activity died down, and later the usual vernal arthritis failed to materialize. However, two months after its expected onset he developed a serious nasal furuncle, and ten days later suffered a moderately severe arthritic bout. During the summer, arthritic symptoms recurred from time to time in association with a rather annoying furunculosis. Under treatment with vaccine and toxoid, both furunculosis and arthritis rapidly improved.

It was observed that, in spite of his great sensitivity to pneumococci, his tolerance for staphylococcal products was rather high. However, it would be unwise to state that the rapid improvement under combined staphylococcus therapy was corollary to the initially low degree of sensitization.

Multiple foci must not be overlooked. The fact that tonsils and teeth have, as usual, been removed does not mean, for example, that the prostate is still normal, or may not even have been the main focus. In one patient a diseased gall-bladder was first suspected through the observation that slight overdosage of vaccine resulted not only in mild increase in arthritic manifestations, but also in short bouts of postprandial distress and flatulence. This patient, incidentally, had previously undergone a tonsillectomy with considerable temporary relief. This tendency of vaccine to cause clinical recurrences in sensitizing foci, while not recommended as a routine means for their detection, is at times of value. For example

A man of forty, who had suffered for eleven years from arthritis of the spine, came for treatment because the process was spreading into the shoulders and knees. All obvious foci had been removed. He gave a story of irritable bowel of twelve years' duration. Stool culture yielded beta-hemolytic streptococci in large numbers. Under intravenous vaccination with the autogenous strain, slow improvement set in. After two months of treatment, a sudden loss of tolerance occurred, manifested by severe reactions after two successive treatments, the second of which consisted of only one-fifth of his usual dose. He was sent to a rhinol-

ogist, who shrank his nasal mucosa thoroughly, and reported absence of clinical sinus infection. Nevertheless, following the examination, the symptoms immediately lessened, and his tolerance was restored.

As a matter of fact, some nasal infection was present, for not only were many staphylococci grown from his sinus ostia, but during the months of March and April treatment was considerably hampered by recrudescence of the infection in the form of a rather obstinate congestive reaction.

Not only may more than one focus be present, but, in addition to grampositive cocci, other organisms may play a part. For example

A girl of twenty-five suffered for three years from slowly progressive arthritis of ankles and knees. She harbored a cervicitis, without other detectable pelvic involvement, and the blood serum gave a positive complement fixation reaction with gonococcal antigen. The cervix was cauterized. Treatment was started with Corbus-Ferry filtrate, with little success. Rhinological examination then revealed bilateral cystic middle turbinates, which were eventually removed. A profuse discharge, laden with staphylococci, appeared from the ethmoid areas. Treatment consisted in alternating injections of Corbus-Ferry filtrate and staphylococcal toxoid, together with the necessary intranasal manipulations. Furthermore, a definite tendency for the joint manifestations to be worse before and during the menstrual period was apparently influenced by the use of prolan for the control of severe dysmenorrhea associated with scanty and irregular menstruation. Under this regime she has steadily improved, to the point where she has been able to resume an occupation which keeps her upon her feet much of the day. Upon several occasions one or the other substance has been deliberately omitted—and each time it has quickly become apparent that best results could be obtained only from the combined treatment. It is a rather unusual fact that this patient's tolerance for gonococcal filtrate has failed to increase, in spite of adequate treatment of the focus, the reason for this is not apparent.

In some cases, sensitivities other than to bacteria may play a part.

A girl of twenty-six was troubled for a year with steadily increasing stiffness of fingers and knees, with slight periarticular swelling. Severe general morning stiffness was a prominent feature. She suffered also

Dosage was accordingly adjusted, and alternating injections of autogenous vaccine and toxoid were administered. Within a few weeks improvement was apparent, and has been rather consistently maintained. This patient is not cured, but she is able to go about her duties with less discomfort and fatigue than at any time for several years.

In view of the moderate success attained with this patient, and inasmuch as autogenous vaccine alone had seemed inadequate, others were subjected to long courses of treatment with alternating doses of vaccine and toxoid. All of them were sensitive to both products. For reasons which will later become apparent, no attempt was made to push beyond the maximum tolerated dose, which was usually discovered within a few weeks. Nothing spectacular has been seen or expected. In the author's private practice, nine of sixteen patients so treated have shown definite improvement. This may seem a small percentage, until it is remembered that *all* of the improved cases had been resistant to other types of therapy. Those individuals have done best whose treatment was begun during the summer or fall months and then carried through the winter. Without exception, they have noted a definite, though at times fluctuating improvement. In others, recurrent sinus activity during March and April has curtailed treatment until the infection could be brought under control. Such activity was always accompanied by recrudescence of symptoms and loss of tolerance to vaccine. In two cases, because of intractable nasal infection, a change of climate was advised, and was followed by prompt improvement, but in neither had vaccination been undertaken until the middle of winter.

In cases such as these, the presence of an undrained or poorly draining nasal focus will prevent satisfactory treatment, in fact, intolerance to the procedure leads to suspicion of its presence. For example, one patient remained persistently refractory and reacted to even minute doses. This discovery of a previously overlooked purulent frontal sinusitis and its proper management resulted rather quickly in a degree of clinical improvement, and concurrently it became possible to vaccinate him satisfactorily.

In certain patients first seen during

the summer months, sinus infection was not apparent, either clinically or roentgenologically. It was not until the association was observed of arthritic relapses with nasal recrudescences that the presence of sinus trouble was suspected. Questioning then revealed the fact that joint manifestations were usually more pronounced during the late winter and spring months, while the summer season might even be a period of comparative well-being. Possibly there exists a low-grade infection of the sinus mucosae, comparable somewhat to that of chronic tonsillitis, which is insufficient to be detected clinically except during periods of heightened activity, but which may serve as a sensitizing focus. Be that as it may, in such patients, at any season of the year, pathogenic organisms, usually *Staphylococcus aureus*, can always be grown, frequently in large numbers, from the ostia of the sinuses below the middle turbinates, or from the interior of such as are accessible to probing. It is probable that into this category fall many of those unfortunates who, because the nasal infection was not apparent upon a single examination and no cultures were taken, have been regarded as having no demonstrable focus, and whose disability has persisted in spite of the usual measures. The fact that the arthritic host is sensitive to these organisms and their products is suggestive etiologically but not conclusive, in view of the known lack of specificity of sensitization to gram-positive cocci. Unfortunately, there is today no known method of demonstrating the causative role of any one strain of bacteria in any one arthritic patient, consequently the evidence must still be indirect and even indefinite, as is that just presented. However, the fact remains that in at least some of those patients, persistent treatment with *staphylococcus* vaccine and toxoid is clinically of value, while the use of hemolytic streptococci is unsatisfactory, inadvisable or even harmful because of intolerance.

Pneumococcal sinus infection has been found to act as a focus. For example

A man of fifty-five suffered every spring from recurring acute arthritis associated with recrudescences of a multiple sinusitis. *Pneumococcus* group IV was isolated in pure culture from the nasal discharges. Be-

solution in one cc ampoules for intramuscular injections, in doses of 05 grams (5 centigrams) and 10 grams (1 decigram). It is administered at weekly intervals until three series, each aggregating 22 grams, have been given. The interval between the first and second series should be not more than six to eight weeks, that between the second and third series may be three to four months. The sedimentation rate is used as a laboratory index of the control of the disease. The average reading before treatment was 418 mm in one hour, gradually falling throughout the months of therapy to a normal or ten mm or less in one hour. Forestier sounded a warning regarding the toxicity of the drug, but did not emphasize the frequent incidence, nor violence of its manifestations.

Our series comprises fifty-two cases. More than fifty per cent have developed toxic symptoms, intolerance, or allergy, necessitating discontinuance of the drug. All who could tolerate it—twenty-five so far—have shown rather startling clinical improvement, a remission of pain after four to six injections, and definite improvement of function with decrease in periarticular thickening at the termination of the first series, although many of these have had some toxic manifestations necessitating interruption of treatment for short periods from time to time.

Transient albuminuria was frequently noted. No cases of nephritis developed. A mild hepatitis occurred in one instance, associated with jaundice. No purpura, but two instances of severe epistaxis were recorded suggesting a disturbance of the hematopoietic system. There were two instances of severe gastroenteritis, ushered in with chills and followed by fever ranging to 103° and 104°F, and marked malaise, lasting a week in one patient, and two weeks in the other. Six or eight have reported experiencing this syndrome in milder forms. At least six have developed corneal ulcers—quite difficult to heal. Three have had a generalized exfoliative dermatitis, one after 19 grams (nineteen decigrams), another after but 15 grams (fifteen centigrams), and the third after 65 grams (sixty-five centigrams) of the first series. Stomatitis, glossitis, and milder forms of dermatitis have been frequently encountered. We record one death.

A female, age fifty-nine, suffered from rheumatoid arthritis of six years duration. After six five-centigram doses (.30 grams total) of myochrysin she developed mental confusion, followed in five days by delusions, great cerebral excitation, stupor, coma, and death. All of the symptoms were cerebral, and in the opinion of the Medical, Neurological, and Ophthalmological departments the condition was one of toxic psychosis-encephalomalacia. Death was caused probably by cerebral thrombosis as a result of

therapy with a heavy metal. There was no autopsy.

As a result of the work so far, despite careful technic, constant laboratory check on blood and urine, use of the identical drug, together with vigilant search and questioning of all patients at each revisit to detect the earliest manifestation of toxicity, we are of the opinion that

1 The dosages advised by Forestier are not tolerated by our patients.

2 Even in small doses the drug is very toxic.

3 Allergic or toxic symptoms can develop so suddenly, and with such small aggregate dosage, as to make this type of therapy definitely hazardous.

4 In its present form it is not a safe therapeutic agent to place in the hands of the medical profession, despite the French optimism as a brief for its innocuousness.

5 The percentage of patients who can tolerate the drug is too small to subject the average early case, in which it allegedly does the most good, to the risk that it entails, especially when we are obtaining equally as good, if not better, percentage rates of arrest with vaccine therapy or filtrates a phase of treatment, by the way, in which the French are far behind us.

6 There is no evidence in Forestier's large series, 550 cases, or in our small series of fifty-two cases, to assume that gold therapy is curative.

7 This may be said in its favor, however, that if a patient is tolerant of the drug it is more likely to produce rapid symptomatic improvement, sometimes a dramatic quiescence, and the remissions are more sustained than by the orthodox methods now in use in this country.

DR. A. S. GORDON, *Brooklyn*—The diversity of opinion and the investigations of the subject from many angles will eventually lead to progress in the field of arthritis. A specific is not necessary. We must remember that during the past twenty-five years a great deal of progress has been made in the management and treatment of tuberculosis and yet we have no specific for the disease. Chronic arthritis is, in many respects, similar to the problem of tuberculosis, both from the medical and social standpoints.

I was especially interested in Dr. Hitchcock's paper on the treatment of infectious arthritis because for the past five years I have been using not only staphylococcic toxin but many varieties of streptococcic toxins, both autogenous and stock, and I am very enthusiastic about this method of therapy. The soluble toxins are much more potent antigens than the bacterial vaccines, and the response produced by them is correspondingly better. However, the patient must be tested to the toxin and the therapeutic dosage correlated with the degree of

from unexplained gastrointestinal upsets. There was no seasonal incidence of symptoms. Thorough examination failed to reveal a clinically infected focus, however, the blood serum yielded a positive complement fixation reaction with gonococcal antigen. Treatment was undertaken with gonococcal filtrate with fair but unsatisfactory results. Inquiry was made into the dietary habits, and it was found that the patient was in the habit of eating large quantities of fish. Elimination of all sea food from the diet resulted within two weeks in marked relief from the stiffness, while the gastrointestinal upsets ceased completely following similar omission of cow's milk. On two subsequent occasions, restoration of fish to the diet was promptly followed by recurrence of stiffness and some swelling. She received a thorough course of treatment with gonococcal filtrate, and did well through the winter until March. A staphylococcal nasal infection then supervened, and at once the old symptoms reappeared. Combined treatment with staphylococcal vaccine and toxoid was followed by rapid relief, and today she is quite free of any distress. She is, however, I am afraid, still subject to recrudescences, given a sufficiently strong infective stimulus. Tentatively, at least, she must be regarded as an example of multiple food and bacterial sensitization.

In another case, in which no decision as to the offending foodstuff could be made from the history, the simple use of a Rowe elimination diet resulted in so much relief that the patient dropped out of sight before the responsible allergin was finally detected. Possibly the occasional success of apparently meaningless food restrictions may result from the unwitting elimination of offending food proteins.

Finally we have the intriguing question as to the role of endocrine upsets. With the gradual development of more accurate methods of study, we hope that some day this role will be accurately delimited.

DR. DONALD E. MCKENNA, *Brooklyn*—I can add little, if anything, to the subject as it has been presented by the readers of these papers, and the able discussers preceding me.

I would like at this time, however, to report on the progress of a small, although carefully selected, group of cases of chronic rheumatoid arthritis treated at The Brooklyn Hospital since February 1935 [fourteen months] with gold sodium thiomalate-myochrysine. It is an aqueous solution of the

For the present, reliance must still be placed upon clinical observations in a field where the imagination is still given rather free rein. Reference has already been made to the girl whose premenstrual and menstrual symptomatic exacerbations were relieved by prolan. In her case the indication for the use of this hormone consisted in the presence of definite hypopituitary stigmata. In another patient, arthritic complaints developed simultaneously with the onset of menopausal symptoms, and were considerably relieved when follicular hormone was administered. In both instances, however, it is an open question whether the arthritis itself was greatly influenced by hormone treatment, or whether the relief of the patient's other complaints did not serve simply to make her more tolerant of her arthritis. Too great caution cannot be employed in the interpretation of results in these and similar cases.

Conclusion

It has not been the purpose of this paper to present a fixed outline of treatment for arthritis. Enough has been said to reveal that this is impossible. Therapy must be fitted to the individual patient, keeping in mind the possibilities of multiple focal infection, of infection not always apparent clinically, but suggested by the history and bacteriologically detectable, of infection with diverse organisms, of complicating non-bacterial allergies, and finally, and rather vaguely, of endocrine upsets. With proper surgical, biological, and eliminative measures, and a good measure of perseverance on the part of patient and physician, the outlook for many of these cases is really not at all entirely hopeless.

Discussion

metal, in all respects similar to that used by Jacques Forestier of Aix-les-Bains, France, who, on a visit to Brooklyn in the fall of 1934 reported there, and elsewhere in this country, the results of six years experience in the treatment of this disease with gold salts. From an analysis of 550 cases he stated that, "this form of therapy gave better results than any previous method employed in France."

For those unfamiliar with the treatment it might be said that the metal is suspended in

THE ECONOMIC PROBLEMS OF PHYSICAL THERAPY

S E BILIK, M D, *New York City*

Physicians, generally appreciate the growing importance of physical therapy and recognize that where indicated it is as specific as anything available in our therapeutic armamentarium. There is hardly a practitioner who has not an office full of expensive physical therapy apparatus. Admittedly, relatively few physicians are qualified to make use of these powerful modalities intelligently and knowingly.

The meager and frequently erroneous instructions supplied by the manufacturers of the apparatus are of little value. Attempts to cull the desired information from text books and periodicals fail, primarily, because lacking the essential background, the tyro in this field finds difficulty separating the wheat from the chaff, and finally because it is always hard to learn correct technic merely by reading printed instructions.

Thus, in the course of time, the average physician establishes a "muddling through" system of his own, based on stray bits of information from various sources. The busy practitioner assigns the task of administering physical therapy to an office aide who may know even less about it than the physician himself—certainly, an undesirable state of affairs, unfair to both the physician and to his patient. The former gets poor results, the latter is the recipient of "gold bricks."

Physical therapy is too valuable and complex a specialty to permit of slipshod or "shot-gun" technic. A thorough grasp of the physiological effects and of the proper method of administration of each modality, is vitally essential to the attainment of beneficial results. The effective use of insulin, digitalis, salvarsan, endocrines, serums, vaccines, etc., depends on correct technic. Wrong technic may produce no results or actual harm. The same holds true with a vengeance in the field of physical therapy.

Where and how is this desirable knowledge of physical therapy to be obtained? Until recently this stepchild of medicine was completely ignored in medical schools. At present, many of the schools

have added instruction in this subject, but instruction so cursory and inadequate as to make it of no lasting or practical value. No time should be lost in placing the teaching of physical therapy on a major basis, at least on a par with that of pharmacology.

Meanwhile, the newly hatched medicos are joining the vast army of practitioners who are using physical therapy without having any worthwhile concept of its theory or practice. An attempt should be made to fill this void by means of an extensive series of postgraduate courses at teaching centers, hospitals, county medical societies, etc. Sporadic lectures are appeasing, but utterly ineffective, merely adding a few more stray bits to one's physical therapy slumgullion. What is wanted is a carefully planned, exhaustive practical presentation of the entire subject.

Assuming the possession of a fairly sound concept of the principles of physical therapy, its effective prescription and administration is not difficult and can, and should be done by the general practitioner—who has the time for it. For physical therapy does take a great deal of the physician's time—a conservative estimate would be an average of one hour per treatment.

The busy physician, appreciating this, frequently prefers to refer his cases in need of physical therapy to those specializing in the latter field. The cases so referred are quite numerous—sufficient to keep comfortably busy a large group of physical therapists (physicians specializing in physical therapy) if

In the vast Metropolitan area with its 14,000 physicians, there are at most twenty physical therapists. In the entire state there are probably five more. I am not considering the variable number of those who merely dabble in the field. Within the past five years, to my knowledge, not a single young physician has entered this specialty. When a recent graduate, who finds physical therapy interesting, asks my advice as to whether he should select it as a specialty, I am compelled in all honesty to dissuade him

allergic sensitivity as shown by the intradermal reaction

Recently I had occasion to demonstrate the following

I selected four patients from the medical ward of the Kings County Hospital, *first* a case of rheumatoid arthritis, *second*, a case of chorea (afebrile), *third*, a case of recurrent rheumatic fever with acute endocarditis, *fourth* a case of recurrent rheumatic fever in the convalescent stage (afebrile). These patients were tested intradermally with the soluble toxins of three strains of hemolytic streptococci—(1) scarlet fever, cultured from the blood of a fatal case of scarlet fever, (2) erysipelas, cultured from the skin lesion of a case of recurrent erysipelas of twenty years duration, (3) a "rheumatic strain," cultured from the throat in the acute stage of a recurrent attack of rheumatic fever before the joint symptoms appeared. As control tests I used Sterile broth in which the streptococci were grown, and the boiled toxins of these organisms. The twenty-four hour reactions were as follows. The case of rheumatoid arthritis showed similar reactions to all three toxins which were read as a moderate reaction in each case (area of erythema, tenderness and induration, two centimeters in diameter). The case of chorea showed a marked reaction to the "rheumatic strain"

(area of erythema, tenderness and induration, four centimeters in diameter) but negative reactions to the scarlet fever and erysipelas strains. In the case of recurrent attack of rheumatic fever with acute endocarditis, all reactions were negative, while the patient in the convalescent stage of the recurrent rheumatic fever attack, the "rheumatic strain" showed a marked reaction (similar to the reaction in the chorea patient), and the scarlet fever and erysipelas strains showed negative reactions. All control reactions were negative, in all patients.

I shall not enter into a discussion of the interpretation of these reactions, but will say that insufficient attention is paid to the significance of such reactions, and the relation of the clinical manifestations to the toxins of the various bacterial strains. Finally, I want to say that entirely too much stress has been laid in the past on the bacteria or the bacteriologic agents of disease, and not enough stress on the victim or the patient behind the disease. The same or similar bacteria may produce different clinical manifestations in different patients depending upon the hereditary and constitutional predisposition of the individual.

COUNTERFEIT FOOD

Worse than the danger of counterfeit cash is the menace of counterfeit food. Arthur Kallet, in his new book called "Counterfeit" (Vanguard Press) remarks that one special difference between money counterfeiting and goods counterfeiting should be pointed out. There are, of course, many differences, most of which would probably establish money counterfeiting as a less serious crime, socially, than goods counterfeiting.

With goods, the counterfeiting—that is, the representation of the goods as something which it actually is not—may be introduced by the manufacturer or by a distributor.

Sometimes, however, the entire job of counterfeiting is done by the retailer. Here it is the butcher shop. Housewives will testify that many butchers turn counterfeiters every time they utter such a word as "tender" or "choice."

Another kind of butcher-shop counterfeiting is practiced by many, though by no means all, butchers, with the aid of a chemical preservative called sodium sulphite. Stale malodorous meat loses its foul odor, and turns a fresh, juicy red when dosed with

sodium sulphite, and is frequently sold as good, fresh meat.

Not only is the meat itself injurious, particularly if eaten rare but the sodium sulphite is a poison which can do considerable injury to the digestive system.

The meat most likely to be preserved (from the garbage can) with sodium sulphite is hamburger, simply because it is easy to make use of left-over and stale scraps by grinding them together with a dose of sulphite. If you must buy chopped meat, never buy ready prepared chopped meat. Order a cut and have it ground before your eyes.

Not only the butcher sins with sodium sulphite. At the "hot dog stand," the hamburger "places," the restaurant or cafeteria you will often get this chemical with your hamburger sandwich.

Some states confiscate sulphited meats when their inspectors find them, and occasionally levy small fines on the offenders. But they are interfering with an excellent source of profit. Successful state control of this evil is, therefore, exceptional.

One of the physicians examining some school children said to a definitely malnourished little girl "Do you like milk?"

Little Girl "Yes."

Doctor "Does mother give you some?"
Little Girl "Sometimes, but we just take a pint a day and we're raising a puppy and it has to have milk."—Contact

multi-colored circular singing loud the praises of this new "Health Institute" and, of course, soliciting your kind patronage. Within a few weeks after opening, the place is mobbed with patients seeking health at bargain counter prices.

Similarly, many medical publications carry advertisements of individuals and institutes specializing in physical therapy (the physician-physical therapist is at a distinct disadvantage in this competitive field in that he is unable to advertise or in any way solicit your patronage). Finally, your friends refer a constant stream of aides and masseurs with glowing recommendations of their qualifications.

As a general rule, the physician refers his patient to a lay technician with some such prescription as "Please give Mrs. Brown physiotherapy for arthritis of the knee." Or, if he happens to be under the temporary spell of some one modality, he is apt to write "Please give Mrs. Smith diathermy to her right foot." These are indeed dangerous prescriptions in that the practitioner is practically asking a lay technician to become a prescribing physician. One must appreciate that there is no cut-and-dried routine in physical therapy—each case calls for a specific combination of modalities. The patient's reaction determines whether the initial prescription will be abided by or will have to be modified. Only a thoroughly qualified physician can prescribe effective physical therapy. It is utterly folly to expect a lay technician, however intelligent, to be able to interpret therapeutic effects and modify them to combat the existing pathology.

A prominent surgeon drops into a clinic I supervise and finding me absent, asks the technician what routine of treatment she would advise for a given case. The girl readily obliges. A few days previously, I had recommended the discharge of this aide because of her poor qualifications. Yet, here is an experienced surgeon, naturally eager to obtain a good result in his case, accepting the advice of a relative ignoramus!

A traumatic surgeon requests the same technician to do a neuromuscular test to determine the 'R D' of a musculospiral nerve involved in a fracture of the humerus. An internist asks the aide to do

a similar test to determine whether the neurological lesion is of central or peripheral origin. Even an experienced physical therapist or an experienced neurologist would find such assignments difficult! It is quite evident that the great mass of physicians think of physical therapy in terms of mere mechanical technique, whereas it is as complex a specialty as there is in medicine.

Meet the "State Registered Physiotherapist." In 1926, a postscript (which should never have been written) to the N. Y. State Medical Act, established certain minimum educational requirements qualifying lay physiotherapists for a state license. Originally, this was to provide for a small group of, supposedly very highly qualified, technicians. Old Man Politics opened the flood-gates and at this date there are 452 "S R P's" of which only thirty-four or eight per cent had the required educational qualifications. A considerable number of these licenses went to a horde of chiropractors and other irregular healers to be used as a cover for their unlawful practice of medicine.

I have before me a professional card presenting on its face the legend

These various methods are used as auxiliary adjuncts for the elimination of disease, affecting the entire system and rejuvenating every organ and part of body involved.

Being a chiropractor does not necessarily disqualify a man from being a good physiotherapist. What does disqualify him is a lack of knowledge of the very fundamentals of physical therapy. During the last few years I have had occasion to examine a considerable number of these "S R P's" for the government. I was amazed to find how meager was their knowledge of physical therapy. Their entire concept may well be characterized as a hodge-podge of disconnected facts and fancies, thoroughly seasoned with chiropractic bunk and bombast.

Many of these men were not physiotherapists when the politicians made these licenses available. They saw an oppor-

For after twenty-six years in physical therapy, I am convinced that under existing circumstances a physician cannot make a decent living in this specialty, and even as "the butcher, the baker, and the candle-stick maker" the medico too must pay attention to the all-important question of economics.

Among the small group of physical therapists mentioned above, are some who have other sources of income enabling them to follow a specialty for which they have a particular liking—these men spend more on their specialty than they earn from it. One or two have had the business acumen and the necessary capital to commercialize their specialized knowledge. Some supplement their meager income from their practice with the salaries received from their hospital connections. The rest struggle along, striving vainly to make the proverbial ends meet. I suppose I ought to mention the many who would have preferred to have stayed in this specialty, but were compelled, through sheer necessity, to turn to other, more lucrative, fields.

As a result, there is a definite scarcity of physical therapists and this scarcity is going to become more acute since, as pointed out, no new men are coming into the field. One of the largest physical therapy clinics in New York, treating close to 500 cases daily, has but one physician to supervise its activities. For years, every effort to interest physicians, young or old, to join the staff has failed. There is apparently no one who is interested in physical therapy as a specialty. The common practice of placing the physical therapy department in charge of an orthopedician, is on a par with heading the department of surgery with an obstetrician.

This scarcity has led to physical therapists accepting multiple hospital connections—not at all a desirable arrangement, since physical therapy demands a great deal of the time of the supervising physician. A man, however capable and energetic, tearing around from one hospital to another, is not very apt to do good work in any of them—the old story of "too many irons in the fire and none of them hot."

It is essential to keep in mind the qualifications of a good physical thera-

pist. Loading the office with a variety of apparatus, gulping voluminous literature, or the superficial knowledge obtained through the medium of the very short courses intermittently promoted by manufacturers of apparatus, will not make a physical therapist any more than the possession of sharp scalpels, a set of Keene's "Surgery" and hours spent in John Erdmann's amphitheater will make a surgeon.

Firstly, a physical therapist must be a darn good physician. Requests for consultations come from every service and from highly qualified specialists. It behooves the "P T" to know something more than the voltage or the frequency of his diathermy machines when he discusses a case of multiple sclerosis with a Dr. Foster Kennedy. He must have a particularly thorough knowledge of surgical, orthopedic, neurological, and general medical conditions. He ought to be a "shark" on pathology, in order to be able to visualize the tissue damage he is asked to repair. Finally, he must know the various divisions of physical therapy and avoid forming hobbies which will quickly brand him as a "crank." Too many physicians are swept off their feet by crack-brained advocates of new panaceas. Right now we are in the midst of the "short-wave" craze. Some of the silly claims put forth by the boosters of this new miracle performer are enough to delight an idiot. The best results in physical therapy are attained through intelligent and effective combination of the various modalities particularly indicated in any given case.

Thus physical therapy is a complex, important, fascinating specialty. Were it financially remunerative, sufficient to assure the physician a comfortable livelihood, many would come in to the field with resultant gain to all concerned.

Throughout the year, the physician is intensively solicited by "institutes", gymnasia, physiotherapists, technicians, masseurs, nurses dabbling in physical therapy, etc. A Coney Island bath-house suddenly blossoms out as the "Baden-Baden of America" featuring every variety of physical therapy at R. H. Macy prices. Full page advertisements in the tabloid newspapers shriek the good news to the populace. The physician is honored with a

Meet the "State Registered Physiotherapist." In 1926, a postscript (which should never have been written) to the N. Y. State Medical Act, established certain minimum educational requirements qualifying lay physiotherapists for a state license. Originally, this was to provide for a small group of, supposedly very highly qualified, technicians. Old Man Politics opened the flood-gates and at this date there are 452 "SRP's" of which only thirty-four or eight per cent had the required educational qualifications. A considerable number of these licenses went to a horde of chiropractors and other irregular healers to be used as a cover for their unlawful practice of medicine.

I have before me a professional card presenting on its face the legend

Actino-therapy Mechano-therapy Electro-therapy Colonic Irrigations Foot Adjustments Spinal Adjustments

These various methods are used as auxiliary adjuvants for the elimination of disease, affecting the entire system and rejuvenating every organ and part of body involved.

Being a chiropractor does not necessarily disqualify a man from being a good physiotherapist. What does disqualify him is a lack of knowledge of the very fundamentals of physical therapy. During the last few years I have had occasion to examine a considerable number of these "SRP's" for the government. I was amazed to find how meager was their knowledge of physical therapy. Their entire concept may well be characterized as a hodge-podge of disconnected facts and fancies, thoroughly seasoned with chiropractic bunk and bombasm.

Many of these men were not physiotherapists when the politicians made these licenses available. They saw an oppor-

tunity to camouflage their irregular and unlawful practice of medicine and grasped it. As for physical therapy, they never knew it and never will know it, if they practice it another twenty years, primarily because of an utter lack of a proper fundamental background.

The law permits these "SRP's" to have their own offices but requires that all patients treated by them, should first be diagnosed and prescribed for by a physician. This stipulation is not at all to their liking. The *Bulletin*, the official organ of the State Society of Physiotherapists, bristles with statements resenting this imposition and reflection on their professional status. John D. Bascomb, the president of the organization in a recent article entitled, "Can the General Practitioner Retard the Progress of the Patient in Various Cases?" argues

There are few general practitioners who can sincerely and intelligently diagnose the important pathological conditions that confront the profession of physiotherapy.

There is something inconsistent in a law that is enforced for the SRP to be under the supervision of a general practitioner who does not understand physiotherapy.

Their contention is, "Physiotherapy is a branch of medicine. The registered physiotherapist should be considered part and parcel of the medical profession in every respect. He is a specialist in the art of physical therapy." Organized into a state society these "SRP's" are using every means known to politics to obtain legislation to place them on an independent basis as "Doctors of Physiotherapy." And these aspirations to form another group of half-baked healers come from a body of men, the great majority of whom—418 out of 452—have never fulfilled the minimum educational requirements of the state, and whose means of obtaining these very desirable state licenses may not stand too close investigation!

Suppose they did possess a thorough knowledge of the technic of physical therapy—would that qualify them to prescribe treatment as they desire to? A correct diagnosis is a pre-requisite to effective therapy. A pharmacist knows how to concoct medications and knows their dosage—better, perhaps, than the physician does, but that is hardly reason enough to create "Doctors of Pharmaceuthery"

with the right to dispense drugs without a physician's prescription. The SRP's in their eagerness to be "Doctor's" with the right of independent practice, are slightly overestimating the value of mere technical skill.

I am going to qualify the rather sweeping condemnation of the "SRP's" by pointing out that a small group of the latter do possess the essential qualifications of good technicians and are ethical in their relationship with the medical profession. Among these, I would particularly include the graduates of the New York University course in physical therapy (This course has been discontinued). Close acquaintanceship with many of the latter group convinces me that they are capable, ethical, and desirous only to serve as aides of the physician in hospitals and offices. They do not seek the right to practice independently as "Doctors of Physiotherapy."

The facts submitted above regarding the "SRP's" are familiar to all concerned with the enforcement of the State Medical Act, and particularly the State Department of Education. It is known that many of these "SRP's" are ignoring the regulations and are accepting patients without bothering to require a physician's prescription. This is particularly true in the physical therapy departments of the numerous, privately owned, "institutes", gymnasia, bath-houses, usually "covered" by a "SRP." If we assume that the object of these establishments is to provide means of conditioning the body with exercise and bathing, then there is no earthly excuse for the availability of powerful physical therapy modalities which can only be used in the treatment of trauma and disease. The facts are that members of these establishments are being treated for all sorts of aches and ills, the supervising physiotherapist doing all the diagnosing and prescribing—a clinic practicing medicine illegally. The authorities are cognizant of this, but have thus far been unable to find effective means of solving the problem. It is one thing to be aware of unlawful activities; it is quite another matter to obtain evidence which will stand up in court. The culprit must be caught "red-handed." At all times criminal investigation and persecution is both ex-

pensive and time-consuming. The one sensible solution would be the abrogation of the present regulations and the passage of new legislation to establish minimum educational and professional qualifications for physiotherapy technicians. The latter should not be permitted to conduct offices of their own in competition with those of physicians, but should be rigidly restricted to service in hospitals and doctor's offices.

As an interesting serio-comic aside, I quote the following bit of news which gave sophisticated New York City a hearty "belly-laugh." Under date of June 22, 1936, the newspapers report

The raided massage parlor, known as the Danish Institute, advertised in the classified telephone directory, claiming "Miss Anna S—, Registered Physiotherapist Massage, Medicinal Packs, Baths, Colonic Irrigations

Highest testimonials from New York's leading physicians

A novel establishment with rare rugs and champagne the wealthier patrons graduated to the floors above where they could obtain treatments not prescribed by any ethical physician. In an upstairs apartment they discovered a highly embarrassed young woman and an equally perturbed male "patient" who had called for treatment on "physician's advice."

The confusion of the pair was intensified by an absence of attire and the presence of a huge, leather blacksnake whip. When Detective C—, began removing his garments, one of the pretty attendants entered the room and began to strip.

The daily income ranged from \$500 to \$1,000. The police are laying plans to raid more such "institutes."

Not recognized nor licensed by our state, in spite of their excellent educational and professional qualifications, is a group of physical therapy technicians organized under the banner of the "American Physiotherapy Association." The nucleus of this group was formed by a splendid type of men and women who served as aides during the war. Earnestly and sincerely cooperating with the medical profession, the A P A has established rigid qualifications for admission. Their ethical standards are of the very highest—they seek to work for, and under the guidance of the physician. Graduates of such splendid schools as Harry Stewart's, R & C, Harvard, Northwestern, etc., they are thoroughly skilled in the

various branches of physical therapy. Yet, they appreciate their limitations and do not attempt to overstep them. In selecting a technician you may with confidence accept those recommended by The American Registry of Physical Therapy Technicians (30 N Michigan Ave., Chicago) allied with the A P A.

Finally, we have the very large group of masseurs. Whether graduates of a European school (which adds glamor but no other virtue) or of one of our own schools, these men and women are capable in direct proportion to their mental fitness and their basic education. They are taught massage, corrective exercise, and hydrotherapy with considerable thoroughness. Their knowledge of electrotherapy is negligible. Close contact with hundreds of masseurs enables me to say that with few exceptions, they are conscientious, earnest, reliable, honest, ethical, and capable—as masseurs. They are not physical therapy technicians. Under proper guidance and supervision, these men and women will do excellent work. We should not expect them to prescribe the kind, duration, and intensity of the massage or exercise indicated in any given condition. This must remain the responsibility of the physician who appreciates the pathology he is dealing with.

Not all "licensed" masseurs are qualified. In New York City, the regulations governing the granting of licenses to masseurs, are rather loosely worded and as a result many a bruiser or ex-bartender who doesn't know a muscle from a liverwurst, is parading around as an "Expert Licensed Masseuse." Therefore, when selecting a masseur, be on your guard—do not be unduly influenced by his physique or Scandinavian "brogue"—find out what school he graduated from.

In summary, my contention is that physical therapy is a specialty of constantly growing importance, that it is desirable that more physicians come into this field, and that it can only be achieved if the profession as a whole, will give its support to these pioneers by referring cases to them rather than to the layman, as has been the rule in the past. The physical therapist will employ properly qualified technicians and will guide and supervise their activities. Your patient will be assured of receiving a routine of

treatment particularly indicated in his case and the treatment will be varied as the progress of the case demands. You will be consulted and your interests will be protected in that there will be no possibility of your patient being "lifted." Finally, it is well to keep in mind that the fees charged by the physical therapist are no higher than those commonly charged by lay technicians.

This is not a personal appeal. I am fortunate in having a bit of an income which makes me independent of my practice. I am in physical therapy because of a sincere liking of this specialty and a thorough conviction of its efficacy in the treatments of human ailments. It is be-

cause of this conviction and an appreciation of the handicaps which face the embryonic physical therapist, that I decided to place the facts before you. I feel confident that you will recognize the honesty of my motives and the justice of my argument.

Incidentally, my understanding is that an almost similar situation exists in the x-ray and the laboratory fields, where physicians thoughtlessly refer their patients to advertising laymen, while your brother physicians in these specialties wait for the occasional crumbs from the thoughtful ones.

667 MADISON AVE.

THE COUNTRY DOCTOR

A country doctor in a little community in Minnesota recently cancelled unpaid bills totalling \$50,000 leaving about \$20,000 unpaid bills on his books. Knowing something about the demand upon the country doctor's time, *The Ulster County News*, of Kingston, ventures the opinion that this lone doctor who reached the news columns of the papers is in no wise an exception.

A country doctor is not like a country electrician, or painter, or carpenter, or mason. These men, experienced in the credit of their neighbors, may refuse to work on a job that promises no payment. In fact, people will not hire the craftsman, as a

general rule, if they haven't the money to pay him. But when little Jack or Jill, or Baby Jim or Jane become ill, the country doctor just has to come—money or no money. And bills pile up.

What is there to do then when bills get old, people move away, folks pass on leaving no estate? The country doctor finds his accounts receivable automatically cancelled. That is, if he ever did put the bills on his books.

A close friend of ours, says the Kingston editor, is a country doctor with his office in an Ulster County town. His office is constantly crowded with people. Frequently he has to leave early in the morning, late at night, forget his breakfast, lunch or dinner—just go—and keep on going, forgetting self and family. No time for vacations. No time for a trip here or there. He's needed right in his own community. He's never said a word about people paying him. He seems to get his reward when little Jack or Jill pulls through from a close call with pneumonia or when Jim or Jane undergoes an operation and is O.K. once more.

No, friend, don't think that when one country doctor jumps into prominence with an announcement that he has cancelled bills, and God bless him for doing it—that he has done something that your own country doctor hasn't done. It all means that there is no more useful friend on earth than the country doctor and folks ought to pay him so he can keep on working and living because when he passes on you are going to miss him. And many of them pass on early in life because they were overworked, undernourished and underpaid.

"What a day! An appendix, gall-stones, tonsils, two babies, measles, mumps, a broken leg, and a dollar!"—Fred Balk in the *Country Gentleman*.

SUBCUTANEOUS RUPTURE OF THE STOMACH

Review of Literature and Report of a Case

NORMAN J WOLF, B A , M D , *Buffalo*

Surgeon, U S Marine Hospital

By subcutaneous rupture of the stomach, a condition to which the term "subparietal" rupture is sometimes applied, is meant the rupture of that organ unassociated with penetrating wounds of the abdominal wall. This excludes such injuries as gunshot and stab wounds, cases in which there is a pre-existing pathological lesion, as ulcer or carcinoma, are also excluded. This type of rupture may be traumatic or spontaneous.

It is by no means a common condition. Sherren¹⁹ reported 270 cases of abdominal contusion at the London Hospital with only five cases of ruptured stomach. Battle²³ reported 165 cases of gastrointestinal injury with no cases of stomach injury. Eisendrath¹⁵ in 1902 reported 143 cases of injury to abdominal viscera with no cases of stomach injury. Petry¹³ in 1896 collected 219 cases of rupture of the gastrointestinal tract with twenty-one cases of ruptured stomach, thirteen traumatic and eight spontaneous. Glassman²⁰ in 1929, in a comprehensive review of the literature, collected fifty-two cases to which he added two of his own.

Surgical Anatomy

The position of the stomach to a great extent protects it from injury and accounts for the few cases of this type of trauma encountered. When empty the stomach lies at the back of the abdominal cavity and is little exposed to any direct force. The left half of the anterior-superior surface is in contact with the diaphragm and covered by the base of the left lung and the 7-8-9th ribs, the right half is in contact with the left and quadrate lobes of the liver, and over a small area with the anterior abdominal wall. The transverse colon may also cross this surface.

Other abdominal viscera are less well-protected and much more susceptible to injury. The intestines lie against the anterior abdominal wall, especially the jejunum and ileum which are most frequently injured. The liver is protected by the thoracic cage, but its large size,

friability and fixity render it liable to injury. The spleen is likewise frequently injured. The kidneys are poorly protected posteriorly and laterally by muscles, and medially are in close contact with the transverse processes and bodies of the vertebrae against which they may be impinged by a localized force. It is due largely to their anatomical positions that we find the liver, spleen, pancreas, intestines, and kidneys much more frequently injured than the stomach.

Mechanism of the Force

The force producing the rupture may be either direct or indirect. The direct force may be circumscribed (i.e. kicks or blows in the epigastrium), or diffuse (i.e. being run over, crushing injuries, falling on abdomen from a height). Indirect forces are those producing a rupture when an individual falls on his head, feet or buttocks (this type of trauma most frequently produces injury to the liver, spleen or kidney). The force may act by a crushing action, the viscus being impinged between the force and the spinal column, by a bursting action, the force being applied on the anterior stomach wall when the organ is distended, or by a tearing action, the viscus being torn at points of attachment.

It can be readily understood how a stomach may be ruptured when great violence is applied such as being run over or falling on the abdomen from a height. But other forces must be brought into play when the trauma is negligible or absent. In these cases there may be a sudden contraction of the abdominal muscles with a decrease in intra-abdominal space and a corresponding increase in intra-abdominal pressure, thus causing the viscus to rupture. Occasionally powerful contractions of the abdominal wall during vomiting may increase intragastric pressure enough to produce a rupture. In cases of so-called spontaneous rupture the force acts from within the viscus. Overdistention of the stomach, produced either by food or the formation of gas, is an

TABLE I.—TRAUMATIC RUPTURE OF THE STOMACH
(Cases collected from the literature)

Author	Reference	Sex	Age	Type of trauma sustained	Signs of External Abdominal Injury	Injury to other viscera	Trauma to stomach (Operative or post mortem findings)	Operation	Time	Result	Remarks
Poland	1	F	9	Run over by wagon wheel	None	Liver	Tear of mucous membrane	No.	Died	9 hrs	Vomiting.
Poland	1	M	Adult	Struck on right side abd. by shaft of dray	None	Spleen	Tear serosa	No.	Died	8 hrs	
Poland	1	M	90	Maltreated and mauled	None	None	Tear anterior wall.	No.	Died	5 days	Vomited blood.
Collins	2	M	13	Fell 12 feet from tree after meal	None	None	2" rent ant. wall near pylorus.	No.	Died	8 hrs	
Buist	3	M	Adult	Fell 20 feet from R. R. trestle	None	Spleen	5" rent post. wall near pylorus.	No.	Died	14 hrs	Vomited blood.
Lunn	4	M	4	Run over by a cab	None	None	Two 1" tears great curv near cardia	No.	Died	4 hrs	Bleeding from nose.
Jackson	5	M	17	Struck on abdomen by piece emery wheel	None	None	Rents near pylorus ant. and post. walls.	No.	Died	8½ hrs	Bloody vomitus
Minor	6	M	10	Run over by a truck.	Abrasion R.L.Q.	Rent in ileum	Rent lesser curva- ture.	No.	Died	12 hrs	
Limont-Page	8	M	31	Hard blow over epigastrium	None	None	Rent ant. wall near 1 es* pylorus.	Yes*	Recovered		*Spontaneous recovery fibrous structure formation & pyloroplasty later
O Farrell Strassmann	11	M	13	Playing with sled	None	None	3" rent post. wall	No.	Died	22 hrs	
	12	M	Adult	Stomach lavage (opium user)	None	None	Multiple mucosal tears lesser curv	No.	Died		
Rehn	14	F	19	Fell from balcony—abdomen struck an iron rail.	None	Spleen	3 incomplete tears, 2 ant. and 1 post. wall.	Yes	5 hrs. Recovered		Vomited blood
Roeques	14	M	Adult	Fell from first floor to pavement.	None	None	6" rent great curv. cardia.	No.	Died	3 hrs	
Murchison	14	Adult	Train wreck		None	Liver and diaphragm	1½" rent mid. great. curv	No.	Died	Immediately	
Erichsen	14	M	Adult	Crushed between cartwheel & post	None	Liver and spleen.	Almost torn across at pylorus.	No.	Died	5 hrs	
Thiery	14			Fell three stories	About pubes.	Bladder	1" rent ant. wall	No.	Died	5 hrs	
Wilson	14			Run over by wagon wheel	None	Liver	2" rent ant. wall near pylorus.	No.	Died	3 hrs	
Andrews	14	M	17	Crushed between cart and wall	None	Spleen	1" rent ant. wall near pylorus.	No.	Died	8 hrs	
Ogston	14			R. R. accident	None	None	Complete tear at pylorus.	No.	Died	Immediately	
Rohner	13	M	38	Fell 12 meters after a meal.	None	None	Rent ant. wall less. curv near pylorus	No.	Died	5 hrs	
Key Aberg	13	M	52	Stomach lavage following 1 gr opium	None	None	Multiple mucosal tears less. curv	No.	Died	6 hrs	
Lippmann	13	F	17	Jumping over a fence.	None	None	Rent ant. wall less. curv	No.	Died	15 days	Immediate pain and feeling of fullness, symptoms became worse 14 days later
Ettmüller	13	F	10	Fell on stick	None	None	(Gastric fistula)	No.	Recovered		Pain and epigastric swelling developed gastric fistula after several months
Ettmüller	13	F	47	Blow on abdomen	None	None	(Gastric fistula to No. pylorus)	No.	Recovered		Painful swelling which developed a gastric fistula, healing after 9 years
Kronlein	13	M	24	Fell from a horse striking abdomen	None	None		No.	Recovered		Developed scar tissue stenosis with adhesions to liver
Groff	7	M	50	Kicked in epigastrium by a horse	Hemorrhage about umbilicus	None	3" rent ant. wall near pylorus.	No.	Died	15 hrs	
Rose	9	M	20	Fell from roof—3 stories.	None	(Fracture skull)	Rent anterior wall	Yes*	4 mos. Recovered		*Laparotomy for obstruction, adhesions to L. lobe of liver with abscess compressing colon.
Rose	9	M	24	Fell against truck struck L. U. Q.	Con- tusion	Pancreas	2" rent post. wall	Yes*	2 wks Recovered		*Tumor mass developed above umbilicus abscess in lesser omental sac.

(CONTINUED FROM PRECEDING PAGE)

Clarion	10	M	16	Crushed bet buffers of R. R. trucks.	Abrasion	Spleen	Tears in mucosa ant and post wall.	Yes	12 hrs	Died	36 hrs	
Winterer	16	M	20	Blow on abdomen while playing football.	None	None	8 cm tear mucosa post wall.	Yes*	3 wks	Recovered		*Laparotomy for recurrent hemorrhage.
Rodocanachi	18	F	6	Fell on abdomen while running	None	None	2" rupture greater curv	Yes	24 hrs.	Recovered		
Singler	20	M	23	Iron casting fell on epigastrium	None	None	Tear almost across at pylorus.	Yes	3 hrs.	Died	10 hrs	
Weeks	21	M	35	Steering wheel of auto struck epigastrium during a collision	None	Rupture post rectus sheath	Tear from lesser to greater curv at pylorus.	Yes	Few hrs	Recovered		
Verze	23	F	10	Fell on steps	None	None	Rent post wall at No. fundus	No		Died	8 hrs	
Pancastelli	26	M		Thrown against cart shaft	Abrasion R.U.Q		Complete division of stomach into two halves.	Yes		Died	17 hrs	
Widgans	27	M	8	Run over by an auto	None	Liver and pancreas.	Rent in pyloric region	Yes	Few hrs.	Recovered		
Neuburger	28	M	Adult	Fall from a height	None	None	Rent ant wall pre-pyloric	Yes	9 hrs.	Died	24 hrs	
Balton	32	M	29	Fell from a ladder struck abdomen on piece of projecting iron	None	None	Rent ant wall near pylorus.	Yes	6 hrs	Recovered		
Scotson	31	F	Adult	Automobile accident	None	None	Rent pyloric region near less. curv	Yes	Few hrs.	Recovered		
Scotson	31	M	Adult	Knocked off a bicycle by a bus	None	None	1" rent less curv near cardia.	Yes	Few hrs.	Recovered		
Glassman	30	M	33	Struck across abdomen by a plank.	Abrasion	Spleen	4" rent ant wall near fundus.	Yes	7 hrs.	Died	15 hrs.	
Glassman	30	M	6	Fell to sidewalk	None	None	3 1/2" rent greater curvature.	Yes		Died	6 hrs.	
Moran	30	M	Child	Run over by a car-rage.	Slight		Stomach cut across.	No				
Storaceo	30	M		Fell from a height		Liver	Rent anterior wall	No				
Ziegler	30	M	23	Crushed bet R. R. cars.	None	None	Incomplete tear ant wall	Yes*	3 wks	Recovered		*Laparotomy for tumor mass and obstruction cent containing 3 liters dark fluid formed at point of rupture
Parry	30	M	60	Struck on abdomen following an explosion	Superficial wounds.	None	4 1/2" rent anterior wall	No		Died	4 hrs.	
Marchetti	30	M	Adult	Thrown against a plank.	None		2" rent less curv near pylorus.	Yes	Few hrs.	Recovered.		
Ipsen	30	M	23	Struck on abdomen by handle bar of a bicycle.	Abrasion R.U.Q	None	1 cm. rent great curv near pylorus.	Yes	Few hrs.	Recovered		
Mattieux	30	F	56	Reaching for a vase set under bed.	None		2" rent at pylorus.	No		Died	3 days	
Wilson	30	F	33	Jumped over a fence after eating	None		2" rent at pylorus	No		Died	18 hrs.	
Revilliod	30	F	28	Fell to floor	None	None	4 cm. tears less curv on ant. and post walls.	No		Died	2 1/2 hrs.	

important factor in these cases Glassman³⁰ believes that the distention paralyzes the nervous mechanism so that the overfilled stomach does not empty, with subsequent fermentation and further dilatation, and eventually rupture occurs. Another theory is that overdistention may interfere with the circulation, producing a softening of the stomach wall and subsequent rupture.

Experimentation

Rupture of the normal stomach has been the subject of considerable experimentation by several writers. Ritter,¹⁴ experimenting with animals, directed a blow with a knobbed stick against the abdominal wall. He frequently produced

a hematoma between the mucosa and submucosa but never produced a rupture. Vanni¹⁴ filled the stomachs of animals and then struck them over this area with a club. He frequently obtained mucosal tears often extending into the muscularis, but no complete rupture. Murdfield²⁹ filled normal human stomachs immediately after death with two-three liters of weak HCl, then added NaHCO₃. He regularly produced a rupture, at least in the mucus membrane. Kay Aberg¹⁷ found that overdistention produced typical injuries to the mucosa along the lesser curvature near the cardia. Further distention produced complete tears along the lesser curvature, the tearing taking place from the inside of the viscus outward (as probably occurs

in cases of spontaneous rupture) He believes that the rupture of the stomach along the lesser curvature when overdistended is due to a mechanical factor, the cone-shaped formation of the stomach Fraenkel¹⁷ after a series of experiments always produced a typical rupture along the lesser curvature but concluded that this was due to an anatomical cause He found that muscle tissue of the lesser curvature had less elasticity than that of the greater curvature and therefore there is a greater resistance to stretching along this region This, together with the fact that there are fewer mucosal folds along the lesser curvature, produced a greater tension on this area during overdistention and consequently it ruptured first

Age and Sex Incidence

In this entire series of cases, forty-two occurred in males and twenty-one in females In the group of traumatic ruptures the male predominates (76%) This is probably due to the fact that they are subject to trauma in general more frequently than women While in the group of spontaneous ruptures, fifty-nine per cent of the cases occurred in women

The age incidence varies widely, it being from four to ninety years in this series with an average age of 28.4 years

Pathogenesis

The forces previously mentioned may produce the following lesions

- 1 Tears of the mucosa
- 2 Tears of the serosa
- 3 Tears of the serosa and muscularis
- 4 Separations between the mucosa and muscularis (hematoma)
- 5 Complete rupture thru all layers

In the series of cases here reported complete rupture occurred in eighty-seven per cent, the most common location being near the pylorus on the anterior wall of the stomach extending down from the lesser curvature Of these cases the rupture was located at the pyloric end in seventy-four per cent of the cases, on the anterior wall in seventy-four per cent, and at or near the lesser curvature in sixty-seven per cent

In addition to the injury of the stomach, especially if due to a diffuse type of trauma, there are associated injuries to other abdominal viscera in about

fifty-five per cent of the cases, the liver and spleen being the organs most frequently involved

Clinical Picture

The clinical picture varies with the type of trauma In tears of the mucosa alone the classic symptom is vomiting of blood Some of these cases go on to traumatic ulcer formation with secondary hemorrhages These ulcers, in contradistinction to the chronic peptic ulcer, heal exceptionally rapidly under treatment Tears involving the serosa alone or the serosa-muscularis evade diagnosis

This series of cases consists chiefly of complete tears thru all layers The usual clinical picture in these cases is not pathognomonic but presents early signs of (1) shock, (2) a perforation of the gastrointestinal tract, or (3) internal hemorrhage The common findings are pain (usually localized early in the epigastrium), abdominal tenderness and muscle rigidity, nausea and vomiting (frequently blood), together with signs of shock and collapse Of these, the most important when it is present is the vomiting of blood Another very valuable aid to diagnosis is a flat roentgenogram of the abdomen with the patient in an upright position If there is a rupture present, a pneumoperitoneum will occur and be evidenced by air between the diaphragm and the upper border of the liver This is usually present before liver dulness is obliterated

If the case does not end fatally as the result of shock and remains untreated, invariably the signs of peritonitis supervene—distention, generalized rigidity, dulness in the flanks, and obliteration of liver dulness Subcutaneous emphysema may occur in spontaneous rupture of the stomach Occasionally there will be a case which goes on to spontaneous recovery Of this series there were seven spontaneous recoveries—four of which were operated on later for complications Here there is a walling off by adhesions with either abscess formation or scar tissue stenosis of the pylorus and subsequent signs of obstruction Occasionally if an abscess or cyst thus formed is left untreated, it will rupture spontaneously thru the abdominal wall forming a gastric fistula

Treatment and Prognosis

The treatment for all cases of complete rupture is immediate laparotomy. In incomplete tears, involving the mucosa or serosa, expectant treatment (observation) is indicated. Of this series as a whole there was a mortality of 71.8 per cent. The following is an analysis of the treatment given:

Non-operated	48 cases
Operated	18 cases
Not given	2 cases
* Spontaneous recoveries	8 cases—16.7%
Operative recoveries	10 cases—55.6%

* Five of these eight cases were operated on later for complications.

Case Report

M. McA., colored, male, age forty-two, post-office employee. On Sept. 25, 1930, about 2:30 A.M. the patient and a helper were tossing mail sacks weighing about eighty pounds from the ground up onto a truck, a distance of about five feet. The end of the sack held by his helper slipped, throwing the entire weight of the sack on the patient, who tossed the sack on the truck turning his body to the left as he did so. He immediately experienced a severe pain in the upper left abdomen. He drank a cup of warm water and vomited. After vomiting, the pain became more severe. He was admitted to the hospital about 4 A.M. He vomited several times shortly after admis-

TABLE II—SPONTANEOUS RUPTURE OF THE STOMACH

Author	Refer- ence	Sex	Age	Inciting Cause	Trauma to Stomach	Operation	Time	Result	Remarks
Lantschner	13	F	72	Vomiting after eating cold meat and drinking 8 cups water and 2 cups tea.	4" rent posterior wall	No		Died 13 hrs.	
Hoffman	13	M	24	Acute dilatation of stomach	3" rent lesser curvature	No		Died	
Chari	13	F	53	Gaseous distention after hearty meal.	10 cm. rent lesser curvature at scar of old ulcer	No		Died	Subcutaneous emphysema. (No evidence of active ulcer.)
Newman	13	M	30	Distention after meal	1/2" rent lesser curvature near cardia.	No		Died 14 1/2 hrs.	Subcutaneous emphysema.
Thomson	13	F	28	Spontaneous epigastric pain while dressing	Rent lesser curvature	No		Died 35 hrs.	
Mickelitz	13	M	27	After drinking (alcoholic fluid in abdominal cavity)	6 cm. rent lesser curvature near cardia.	Yes	Within 24 hrs.	Died 27 hrs.	
Steinmann	22	F	28	Meal of sauerkraut	3" rent posterior wall	Yes		Recovered.	
Verse	23	F	32	Heavy meal after having diarrhea a few days.	Small rent anterior wall.	Yes		Died 24 hrs.	
Frubese	25	F	19	Acute distention	8 cm. rent anterior wall near greater curvature	No		Died	
Gill	24	F	16	Acute dilatation	1" rent anterior wall lesser curvature	No		Died	
Murdfield	29	M	39	Taking soda bicarb. after drinking	Rent lesser curvature near cardia.	No		Died	
Carson	30	M	20	Hearty meal	2 1/2" rent greater curvature at cardia.	No		Died 15 hrs.	
Meyer Leube	30	M	37	After eating rye bread and new beer	4" rent at fundus	No		Died 2 1/2 hrs.	Subcutaneous emphysema
Darenberger	30	M	25	Acute dilatation	Rent at fundus	No		Died 16 hrs.	
Mosnard	30	F	29	Hearty meal of sauerkraut and pork.	Serosal tears lesser curvature, mucosal tears at fundus.	No		Died 9 hrs.	
Bosch	30	F	47	Hearty meal	1 cm. rent anterior wall lesser curvature.	No		Died 3 1/2 hrs.	Subcutaneous emphysema.
Knudrat	30	F	Child	Hearty meal	2 1/2" rent at fundus	No		Died Few hrs.	

Thus we have a non-operative mortality of 83.3 per cent as compared to an operative mortality of 44.4 per cent.

Of the cases operated on, nine of the ten recoveries were operated on within six hours of the injury, the eight cases which died were all operated on within twelve hours except one. Seven of the eight deaths occurred within twenty-four hours after the injury. Sixty per cent of the deaths of unoperated cases occurred within twelve hours and eighty-eight per cent within twenty-four hours after the injury.

son to the hospital, once the vomitus was blood-streaked. He had eaten a light lunch about four hours previously and had felt perfectly well up to the time of the injury, giving no history of any previous gastric complaints. Furthermore he gave no other history of injury than the torsion of his body to the left in tossing the mail sack on the truck.

At the time of admission to the hospital, he was not acutely ill, temperature was 97° F, pulse 110, respirations 24, complained of pain in left upper abdomen, generalized abdominal tenderness most marked in the epigastrium, and left upper abdomen, slight rigidity of the upper half

of the left rectus muscle. He was given $\frac{1}{4}$ grain of morphine by hypo and rested comfortably the remainder of the night.

Sept 25, 10 A M temperature 98.6° F, pulse 75, respirations 20, resting comfortably, no vomiting, taking nothing by mouth, diffuse tenderness throughout abdomen most marked in the right lower quadrant, slight spasm of upper left rectus, no distention, no change in liver dullness.

3 P M temperature 100.0° F, pulse 80, respirations 24, leukocytes had increased to 11,000 with eighty per cent polys, abdomen slightly distended, absence of liver dullness, tenderness more marked with considerable spasm of both recti muscles. Laparotomy advised.

Operation Under ether anesthesia an upper right rectus incision was made. On opening the peritoneum there was a gush of escaping gas. Both the large and small

bowel were moderately distended and the serosa slightly injected. There was a small amount of brownish fluid in the upper peritoneal cavity. The stomach was practically empty and presented a rupture about two inches long extending downward from the lesser curvature on the anterior wall about two inches from the pylorus. This rupture extended thru the serosa and muscularis with the herniated mucosa presenting several smaller perforations. The surrounding tissue presented no evidence of any pre-existing pathology. The rupture was closed with Lembert sutures and the abdominal wall closed without drainage.

The patient made an uneventful recovery and was discharged from the hospital on Nov. 6. He was last seen in January 1935 up to which time he had been free of all gastric symptoms.

DANGER IN STALE COD LIVER OIL

The deterioration of cod liver oil is the subject of an article by Dr. D. V. Whipple in the *Journal of Pediatrics*. He notes that heat, air, and light are the three factors which contribute to spoilage of cod liver oil and destruction of its vitamin A. Vitamin D is unimpaired by these factors.

Samples of cod liver oil from a number of institutions and homes were analyzed to determine whether or not much spoilage existed. It was found that most institu-

tions did not realize the importance of keeping cod liver oil in a cool, dark place, exposed to as little air as possible.

Reputable brands of cod liver oil kept in refrigerators at home and bought in relatively small quantities kept without any sign of deterioration.

The author believes that many of the digestive upsets of children attributed to cod liver oil are the result of a rancid product which has been given to the child.

ANOTHER KIND OF ITALIAN VICTORY

The good health of the Italian troops in the Ethiopian campaign was extraordinary, say advices from Rome. There were "few cases and few deaths" from malaria, no deaths from dysentery, no epidemics of

typhus, typhoid, or recurrent fevers, no cases of cholera or plague, few cases of beriberi and no scurvy. Sir Aldo Castellani, tropical disease specialist, is in charge of the medical service.

DIFFERENTIAL DIAGNOSIS OF CONDITIONS ASSOCIATED WITH SUGAR EXCRETION

WILLIAM G. EXTON, M.D., *New York City*

From the Laboratory and Longevity Service of The Prudential Insurance Company of America, Newark, N. J.

Of the many conditions characterized by urinary reducing substances, diabetes mellitus is the most frequent and serious, and more mistakes are made in its diagnosis than are generally realized. The mistakes are of two kinds: failures to diagnose, and false diagnoses of diabetes. They may be illustrated by recent cases.

A twenty-nine year old woman gave birth to her third child. Pregnancy, labor, and baby were apparently normal. Thirty hours after confinement the mother developed severe headache and nausea, with a severely itching skin eruption over back and buttocks, and the child developed indigestion. Examination of the mother revealed marked acidosis with blood sugar over 300 mgs. In this case a competent obstetrician failed to diagnose severe diabetes because he conjectured that the positive Benedict reactions seen in three specimens of her urine were caused by lactose.

A forty-eight year old lawyer consulted his physician about feeling tired and nervous. Finding him overweight and overworked, less food and work and more exercise and recreation were prescribed. When two weeks of this treatment proved ineffective, a vacation was ordered. Forty-eight hours later the man was found unconscious and rushed to a hospital where he responded to treatment for diabetic coma. Two specimens of his urine reduced Benedict's test so slightly that his excellent physician was sure "no one would have thought of diabetes."

A thirty-five year old engineer submitted a specimen for periodic analysis. It showed a marked Benedict's reaction, and when a second specimen showed 0.7 per cent reduction he was advised to give the reports to his physician. Shortly afterwards he reported being under treatment for diabetes. A year later his urine showed over one per cent reduction, and it appeared that after following a rigid diet for several months without much effect on the sugar in his urine he started but soon stopped taking insulin because he felt better without any treatment at all. A tolerance test was then made which turned out normal, and every-

body was happy with a diagnosis of renal glycosuria. Thereafter for eleven years the man's urine was examined at least once a year, never showing less than 0.4 per cent reduction. Last year a new method disclosed that he had fructosuria.

In line with this case, it may be noted that during the past year more than a dozen cases of pentosuria or fructosuria have come to our attention which had been diagnosed as renal glycosuria. These cases are therefore not at all exceptional. On the contrary, they are typical of similar mistakes which are made every day and which seem to be increasing in number as a by-result of the growth of life insurance, employment, and periodic health examinations.

When one looks into the cases for an explanation, it becomes perfectly clear that the mistakes are traceable directly to limitations of our clinical tests. As is well-known, our tests do not distinguish between glucose—the only sugar involved in diabetes—and other sugars that may occur in urine, not even between the sugars and numerous nonsugar substances which reduce our reagents because they happen to have an aldehyde or ketose group in their molecules. The fact that they all look just like glucose in a test tube when reduction takes place compels physicians to guess the meaning of positive reduction tests. In this situation mistakes in diagnosis are, of course, inevitable.

Reduction Rate Sugar Method

Some years ago various observations^{1, 2} suggested an inquiry into the behavior of urinary sugars under different conditions of reagents, heating, etc. The results proved very consistent, and those of an experiment with a di-sodium-di-nitro-salicylate reagent are shown in Chart I. In this experiment a number of similar samples of watery solutions of different pure

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 29, 1936.

sugars were heated with the reagent at different temperatures for five minutes. The partial reductions thus obtained were then measured and plotted.

It strikes one immediately that these curves would prevent an obstetrician from mistaking lactose for glucose, or a physician glucose for fructose because they show so plainly that lactose reduces more slowly and fructose faster than glucose. The data show the different temperatures at which the various sugars begin to reduce the reagent, and the partial reductions of the reagent by each sugar at temperatures lower than those

necessary for complete reduction. Thus, about fifty per cent of the commonest variety of pentose reduces at 30° C, while the same reductions of fructose, glucose, and lactose require considerably higher temperatures—about 55°, 65°, and 75° C respectively. When this experiment is repeated on urines instead of pure sugar solutions, the same results obtain as illustrated by the measurements of five urines seen in the accompanying table.

TABLE I—IDENTIFICATION AND MEASUREMENT OF SUGARS FOUND IN URINE SAMPLES

Temp. C	Glucose		Fructose		Galactose		Aldo-		Keto-		C
	Mg	%	Mg	%	Mg	%	Mg	%	Mg	%	
30	0	0	0	0	0	0	0	0	0	0	43
40	0	0	0	0	0	0	0	0	0	0	67
45	0	0	0.5	15	0	0	0	0	0	0	74
50	0	0	1.1	37	0	0	0	0	0	0	
55	1.0	18	1.4	47	0	0	0.3	15			89
60	1.9	33	1.8	60	0.6	15	0.8	35	2.8		
65	2.9	53			1.8	44	1.2	60			
70	4.1	75	2.5	83	2.0	64					
75	5.0	91			3.4	84	1.9	80	3.0		98
100	5.5	100	3.0	100	4.0	100	2.4	100	3.1	100	

CHART I

CHART II

These and other experiments prove that its partial reductions actually determine the rate or velocity at which a sugar reduces the reagent, that different sugars reduce the reagent at different rates, and that its reduction rate is characteristic for each sugar, also that the margins between their reduction rates are sufficient to identify the sugars.

In these experiments it will have been observed that the time of heating was kept constant and the temperature was variable. In attempts to apply the principle to routine work, however, it was found that similar results could be had far more conveniently by reversing this and making time variable and temperature constant. The same data obtained in this simpler way are shown in Chart II.

This chart has been employed in the routine work of the Prudential Laboratory during the past year, and besides the sugars, shows other reducing substances which are found repeatedly.

In this, like the preceding chart, it is evident that the various reducing substances are distinguishable by their reduction rates. The method is very simple and quick. A mixture of urine and reagent is divided into two equal samples. One is heated six and the other ten minutes at 60° C and the reductions

Fig 1 Electro-Scopometer

measured One of the samples is then heated five minutes at 100° C for the total reduction The measurements are made with extraordinary accuracy and ease with a universal Electro-Scopometer (Fig 1)

Opposite the Scopometer scale readings on a calibration like that shown in Chart III, the corresponding sugar values are found in terms of glucose and the six and ten minute reduction rates calculated

When the method was put into routine practice, the results proved so interesting, and in many instances so puzzling, that some system of checks or controls was indicated It was therefore run along with six confirmatory tests on a series of reducing urines from 1000 consecutive individuals These included applicants for life insurance, patrons of the Prudential Longevity Service, and employees in the care of the Prudential Infirmary i e, well and ambulant sick adults from all over the United States and Canada

Every urine received in the laboratory was tested with Benedict's qualitative copper reagent and the results rigidly interpreted according to Benedict's original directions, but only one specimen (the first) from each individual is included in the series Besides Benedict's and the reduction rate methods, the following other tests were applied to every urine phenylhydrazin test and tests for pentose, fructose, polysaccharides, and glucuronic acid

As the methods are treated in detail in another paper,³ it will be needless to say more about them here than that some of them are new and that the phenylhydrazin test was used with repeated crystallizations in this series merely to determine the presence or absence of osazones regardless of crystal form It seems anachronistic that no better clinical method now exists for differentiating between sugars and nonsugars It may also be noted that other methods like fermentation, hydrolysis, melting points of osazones, etc, were also employed in special cases

Results The Glucose Reductions

The distribution curve seen in Chart IV shows the concentrations of the reducing substances found in the thousand

specimens It is interesting to find that over sixty-five per cent of the reductions ran 0.5 per cent or less with a peak between 0.2 and 0.3 per cent The lower

CHART IV

CHART V — DISTRIBUTION OF GLUCOSE AND NON-GLUCOSE REDUCTIONS

CHART VI

Responses of 10 normal males and 10 normal females (ages 19-48) to one 75 gram and two 50 gram doses of glucose. Note decline in blood sugar after second dose of glucose—no sugar in urine

CHART VII

Mild diabetes showing atypical result of older test due to irregular absorption and typical result of new test

peak between one and two per cent probably reflects the confirmed diabetics who apply for life insurance. Separating the material at one per cent it appears that only twenty per cent of the specimens reduced more than this.

In its special relation to the diagnosis of diabetes, the material is most instructive when the glucose reducing urines are separated from the nonglucose reducing urines, as seen in Chart V.

This separation shows that while glucose caused ninety-seven per cent of the two hundred reductions which ran over one per cent, it caused only sixty per cent of the eight hundred reductions which ran one per cent or less. As somewhat over ten per cent of the glucose cases turn out to be renal or alimentary or some other form of nondiabetic glucosuria, it is evident that about half of the eight hundred urines containing one per cent or less of glucose came from diabetics and half from nondiabetics.

Since the chances of correctly guessing whether these positive reduction tests mean glucose or something else seem no better than even, it is clear that the only safe way to avoid mistakes in diagnosis is to establish the presence or absence of glucose in urines which give positive reduction tests.

At this point it may be well to emphasize that other criteria, which many seem to use, are futile. Thus, neither the intermittence nor the amount of a reduction has any diagnostic value, because many diabetics excrete sugar only intermittently while many nondiabetics excrete sugar persistently. Even more common are the mistakes which result from believing that smaller reductions point to other conditions and only the larger to diabetes, because the truth is that the slightest perceptible reduction, if caused by glucose, may be just as indicative of diabetes as the largest.

When glucose is excluded as the cause of a positive reduction test, diabetes falls out of diagnostic consideration automatically. On the other hand, when glucose is established as the cause of a positive reduction, it becomes necessary to differentiate between diabetes and the various nondiabetic glucosurias.

The One-Hour Two-Dose Dextrose Tolerance Test

For this differentiation there is no better clinical means than an alimentary glucose tolerance test, and the advantages of always making such tests promptly, particularly before beginning dietetic or any other kind of treatment are many. A newer procedure, the one-hour two-dose dextrose tolerance test,⁴ seems to be superior to older methods. It is based on the

paradoxical law of Allen "Whereas in normal individuals the more sugar given the more is utilized, the reverse is true in diabetes" Physiologists⁵ have interpreted this as meaning that the first dose of glucose stimulates the insulin-glycogen mechanism to such activity that the normal organism is then able to deal with any amount of glucose without becoming hyperglycemic, while diabetics react with distinct hyperglycemia because the insulin-glycogen mechanism fails

According to Kelly, Beardwood, and Fowler⁶

Because of its relative simplicity, its economy of time both from the standpoint of patient and laboratory, its more specific character, its avoidance of equivocal results, we are of the opinion that it will eventually replace the older methods

The more specific and sensitive results of the one-hour two-dose test are related not only to the physiology underlying the paradoxical law, but also to better adjustment of glucose to absorption rate by giving less concentrated and more digestible solutions of glucose and to the elimination of emotional and other extraneous influences by its shorter period

The test is performed by dissolving one hundred grams of glucose in about 650 c.c. of water. This solution is then flavored with lemon and divided into two equal doses containing fifty grams of glucose in about a fifteen per cent solution, which are served cold and are easy to drink within a minute. Also keep at hand three containers with preservative against glucolysis for the blood specimens and three containers for the urine specimens, making it a point when collecting these to have subjects empty the bladder as completely as possible. The following steps are taken after a fast, preferably overnight

1 Collect blood and urine (A) samples and give the first dose of glucose, allowing one to two minutes for its ingestion

2 Thirty minutes after ingestion of the glucose, collect blood (B) sample and give the second dose of glucose, allowing one to two minutes for its ingestion

3 Thirty minutes after the ingestion of the second dose of glucose, collect blood and urine (C) samples. The third urine container is given the subject for a sample of the next urine voided

When the results are plotted (Chart VI), the interpretation of the first part of the curve, that is the part which includes the fasting and thirty minute samples, is exactly the same as the interpretation of the same part of the curve of the older procedures, and the same deduc-

CHART VIII

Typical results of both tests in more severe diabetes i.e. same criteria as mild diabetes but higher sugar values related to the severity of the disease also tendency to high and changing renal threshold for glucose

CHART IX

Renal glycosuria. Blood sugar does not reach diabetic level after second dose of glucose.

CHART X

In alimentary glycosuria there is no sugar in fast-
ing urine but definite amounts after ingestion of
glucose. The new test sharply distinguishes between
this condition and diabetes by fall in blood sugar after
second dose of glucose instead of the rise characteristic
of diabetes

tions are accordingly drawn from the
blood and urine sugar values. The inter-
pretation of the second part of the curve,
the part which includes the thirty and
sixty minute values, is not at all like that
of the older tests, as illustrated by the
following cases

The typical criteria of normal responses
to the one-hour two-dose test are, therefore
(1) a fasting blood sugar within the normal

CHART XI

Nervous and irregular menses. Under treatment
for thyroid trouble, sugar in urine occasionally. New
test definitely excludes a diabetic tendency older test
does not

limits of the particular blood sugar method
employed, (2) a rise in blood sugar which
does not exceed seventy-five mgm in the
thirty minute sample, (3) the blood sugar
in the sixty minute sample is less, the same,
or does not exceed the thirty minute sample
by more than five mg, and (4) all urine
samples are negative to Benedict's test.

From Charts VII and VIII, it is evident
that the criteria for determining diabetes
in the one-hour two-dose test are a more
or less steep rise of not less than ten mg
of blood sugar in the sixty minute sample
following the second dose of glucose and
the relation of blood and urine sugar values
to the severity of the disease.

The criteria of the new test for renal
glycosuria (Chart IX) are, therefore blood

case, emotional disturbance related to secret marriage
and early pregnancy. Older test indicates diabetic
tendency new test does not.

sugars which follow the normal course, or
in any event never reach the diabetic level,
and sugar in all urine specimens

The criteria of alimentary glycosuria
(Chart X) are, therefore a sugar-free
urine after fasting with sugar in the final
urine and blood sugars that follow the nor-
mal curve even when the level is higher
than normal (Charts XI and XII)

Results The Nonglucose Reductions

With the differential diagnosis of the
glucose cases settled in the manner out-
lined, the nonglucose cases remain for
consideration. Chart XIII shows their
distribution in this series

The large number of sugar mixtures,
about one-fourth of all of the reductions

"off", as we called them when they did not point to a known reducing substance, the phenylhydrazin test gave atypical crystals which were familiar although never satisfactorily identified. In fact, a considerable conflicting literature has resulted from attempts to explain these crystals in different ways, but their identity was definitely established by experiences in the course of this study.

In running a glucose tolerance test on a case of known keto-pentosuria the fasting urine gave the reduction rates of ketopentose and the crystals seen in Fig 2A. After ingestion of glucose the urine gave "off" reduction rates and the crystals in Fig 2B. Later when the glucose was excreted, the urine again gave ketopentose rates and the crystals in Fig 2A.

The results of a glucose tolerance test on the urine of a keto-pentosuria case is shown in Table II.

TABLE II

Urine	Sugar	Excretion	Reduction Rates	Interpretation
Fasting	0.5%	150 mg/Hr	85/90	Keto-Pentose
Final	0.5%	243 mg/Hr	70/80	150 mg Pentose 93 mg Glucose

In running a galactose tolerance test on a case of suspected drug poisoning, the fasting urine was negative to Benedict's and phenylhydrazin tests. One hour after the ingestion of forty grams of galactose the urine reduced, gave galactose reduction rates and the crystals seen in Fig 3A, which were taken to be galactosazones. The urine passed during the next two hours gave "off" reduction rates and the crystals seen in Fig 3B which, it will be noted, are the same as those seen in the intermediate urine of the foregoing pentosuria case. An hour later the urine gave the reduction factors of glucose and the crystals seen in Fig 3C, which were taken to be glucosazones.

Following these experiences, tests were run on different concentrations of mixtures of pure sugars, first pentose plus glucose and galactose plus glucose, then various other sugar mixtures, and the crystals in question were easily obtained with almost all of them.

The reduction rates of extracts of some of the more common fruits and vegetables are shown in Chart XIV, and the phenylsazones obtained from the same extracts in Fig 4.

When the different extracts were fed to normal young adults, all of the urines gave "off" reduction rates and the crystals seen in Fig 5.

The reduction rates of the more popular light wines, beers, and soft drinks show other varieties of sugars. Besides these, a check-up of the materials in ordinary diets reveals an unsuspected richness and variety of carbohydrates which tend to be excreted because they do not yield their sugars readily in the processes of digestion and assimilation.

Thus, the occurrence of mixed sugars in urine may be explained in several ways. In the first place, as is well-known, nor-

Fig 4 Phenylsazones from extracts

mal organisms utilize and store glucose to such an extent that they are able to handle almost unlimited amounts before it appears in the urine. Under usual American conditions, sugars enter the body as glucose, cane sugar or starch. Hydrolysis of cane sugar produces invert sugar, i.e., mixtures of glucose and fructose, and digestion of starch maltose. In comparison with glucose, fructose, and maltose the organism finds other sugars more or less unusable and excretes them at lower levels of concentration in the blood. The presence of sugar mixtures in some urines is therefore referable to dietary and digestive conditions.

Another explanation is not so simple because it depends on renal conditions which are not yet thoroughly understood, not even in the case of the mechanism of renal glycosuria which is only partly explained by a lower than normal threshold for glucose. In the pentosuria case it was seen that a mixture of pentose and glucose was excreted after the ingestion of glucose with no hyperglycemia to explain how glucose got into the urine. In the other case whose renal threshold for glucose could be assumed to be intact because his fasting urine was free from

reducing substances, it was seen that glucose was excreted for hours after the ingestion of galactose. Galactose appeared first, then a mixture of galactose and glucose, and finally pure glucose. Another galactose tolerance case gave somewhat different results because the first urine contained sugar mixtures and the later urine pure galactose. Cases like

Fig 5 Phenyllosazones from urine

these raise questions of practical importance concerning renal function and pathology which our present knowledge does not satisfactorily answer, although much pertinent information is available. Thus, in flushing frogs' kidneys, Hamburger and others⁷ found the renal threshold for glucose very sensitive to differences in the composition of the flushing media which by slight alterations made the frogs'

kidneys permeable or impermeable for glucose. There are also clinical observations which suggest that individual differences in the body fluids affect the renal threshold. At the present time one can do no more than surmise that glucose, and probably fructose too, "leak" through the kidneys when unusable sugars are being excreted, and that the unusable sugars are excreted with them when glucose and fructose are being excreted. This accords with our definite impression that glucose or fructose is usually, if not invariably, one of the components of mixtures of excreted sugars. The significance of mixed urinary sugars seems therefore referable to differences in physiology or pathology as well as to dietary or digestive accidents or habits. When glucose preponderates in a mixture, however, it is safer to determine its significance in the same way one does when glucose alone is found in the urine.

Conclusions

Experience in reporting positive urinary reduction tests as glucose and other sugars (pentose, lactose, etc.), mixed sugars, i.e., nonsugars (vitamin C, glycuronic acid, etc.) and unidentified reducing substances demonstrates that it is unsafe to assume that glucose, or indeed any other sugar, is the cause of a positive reduction test, especially when concentrations run one per cent or less. A positive reduction test, therefore, calls for a determination of the cause of the reduction, and if it be glucose, for a prompt glucose tolerance test.

With such a rule of practice, the methods herein outlined make it practicable to prevent mistakes in diagnosis which were hitherto unavoidable.

ALLERGY

Perhaps nothing has given rise to more confusion than the word allergy. No two men seem to use it in quite the same way. To one man it seems to mean a sensitivity to some certain substance. To another it seems to mean every disturbance in sen-

sitivity of any sort whatever. To many others it seems to mean nothing definite but only that if they use the word, even without sense, they are keeping up with the times.—From "Progress in Diseases of the Skin."

COOPERATION OF PATIENTS IN THE EARLY DIAGNOSIS AND TREATMENT OF PULMONARY TUBERCULOSIS

JOHN H. KORNS, M.D., *Olcan*

From the Callaraugus County Department of Health

Of the many problems with which physicians are concerned none is more baffling or more intriguing to many of them than that of bringing about early diagnosis of pulmonary tuberculosis and intelligent cooperation in its treatment. Inasmuch as opportunity has been given the writer for the past eight years to study tuberculosis case histories in this county and to have personal contact with nearly all those dying from tuberculosis, it is thought that certain data may well be brought together for analysis to see what light, if any, can be thrown upon the above problems.

It may be stated at the outset that there is little ground for discouragement regarding the tuberculosis situation in Callaraugus County. The resident mortality rate from tuberculosis, all forms, decreased from 72.6 per 100,000 in 1923 to 48.5 in 1928, and down to 20.6 in 1935. The table shows that fewer cases of serious pulmonary tuberculosis are being found now than were found eight years ago, although the death rate is dropping faster than the case rate.

The table shows that about forty per cent of the new pulmonary cases found in the past eight years have been in the minimal stage at the time of diagnosis. The proportion of minimal cases from year to year has remained rather constant, while the proportion of advanced cases has slightly decreased. During these years intensive x-ray surveys of various groups have been made and a diagnostic and consultative service with portable x-ray equipment have been available throughout the county. The rapid progressive drop in the mortality rate in spite of the failure of the proportion of minimal cases to increase suggests that possibly the solution of the problem of tuberculosis eventually will lie not so much in early diagnosis as in prompt diagnosis and isolation of open cases to minimize contacts after these cases become communicable. Isolation and insti-

tutional care of open cases has been consistently practiced in this county for at least thirteen years and it is felt that this procedure is beginning to yield results. The incidence of positive tuberculin reactors under age sixteen has decreased markedly in the past eight years. On December 31, 1935 there were known to the Bureau of Tuberculosis only three positive sputum patients who were not or had not been in sanatoria. The population of the county is about 72,000.

Whether the medical profession will in the future rely chiefly upon early diagnosis or upon isolation of open cases, or upon both plans, it is certain that a large amount of cooperation on the part of the patient and the family will always be necessary. One does not need to probe into the records or into one's memory very far to bring to light numerous instances of failure on the part of patients to take advantage of all that medical science has to offer, and it is with the hope of adding to our information as to the causes for this non-cooperation that these remarks are written. They are written by and from the standpoint of an administrative officer in tuberculosis prevention and therapy.

In general the tuberculosis deaths may be considered the evidence of failure and the recoveries the evidence of success on the part of the medical profession or of the administrative health organization. This is true in spite of the fact that a fair proportion of cases die or recover regardless of the patient's cooperation in diagnosis and treatment. Therefore it is with the deaths that this article is primarily concerned.

In the past eight years there have been 146 bona fide tuberculosis deaths in the county about which fairly adequate information has been collected by the Bureau of Tuberculosis either directly or through the family physician. The term "bona fide" is based not merely upon the death certificate, which occa-

*Read at the Annual Meeting of the Callaraugus County Medical Society
Ellicottville, June 2, 1936*

sionally has been found unreliable, but upon laboratory examination or other incontrovertible evidence. Analysis of these 146 deaths from the standpoint of cooperation in diagnosis and treatment shows twenty to have had early diagnosis and reasonably adequate treatment, twenty-five to have had late diagnosis apparently due to failure on the part of the physician, forty-five to have had late diagnosis on account of delay by the patient to consult a physician, and finally fifty-six to have had fairly early diagnosis but to have failed thereafter to cooperate in treatment. Thus 101 or sixty-nine per cent of those who died

cases found in the county last year were diagnosed by physicians or referred by them directly to the Bureau's clinic for diagnosis. Sputum specimens in large numbers are submitted by physicians to the county laboratory, and nearly all of them are negative for tubercle bacilli. These facts indicate that the physicians are on the look-out for tuberculosis, although it is a disease which is becoming uncommon in this community. There is, of course, the exceptional patient who is assured by the physician on the strength of a negative sputum and x-ray film that no tuberculosis is present but who later develops definite lesions. Whether or not a definite source of exposure is known, if the patient's symptoms are suggestive, a

TABLE I—PULMONARY TUBERCULOSIS CASES DIAGNOSED IN CATTARAUGUS COUNTY 1928-1935
(All Sources and According to Stages)

Year	Minimal	Moderately Advanced	Advanced	Total
1928	29	25	30	84
1929	34 8%	20 4%	20 6%	74
1930	30	12	18	60
1931	31 2%	19 4%	22 3%	72
1932	27	23	16	66
1933	23 6%	21 9%	16 3%	60
1934	27	20	20	67
1935	20 4%	19 7%	13 7%	52
Total	221 3%	159 7%	155 0%	535

either were diagnosed late through their neglect to consult a physician or they failed to accept professional advice after a rather early diagnosis. In this connection it is frequently observed that a patient who cooperates poorly for a time after an early diagnosis will in desperation follow minutely all instructions later on when invalidism has set in. Such patients are classed here with those not cooperating.

Certain impressions are gained from this analysis.

1 Twenty patients or 13.7 per cent of the 146 died from tuberculosis in spite of an early diagnosis and reasonably adequate treatment, and it is fair to assume that some of the remaining 126 persons might not have been saved had all controllable circumstances been ideal for recovery.

2 The family physician comes in for less blame than is sometimes attached to him. It is the writer's belief that with few exceptions the practicing physicians in this county make reasonable use of modern means for diagnosing tuberculosis. Almost two-thirds of the new pulmonary

physician will do well to urge another x-ray examination soon provided symptoms continue.

3 Fifty-six, or 38.2 per cent of those who die have shown reluctance, amounting to refusal, at the time of diagnosis, to believe the doctor or to follow his advice. If to these are added the forty-five or 30.8 per cent who consulted a physician only after the disease had become advanced one finds that about seventy per cent, for one reason or another apparently failed to be convinced that serious tuberculosis was present until it had reached an incurable stage.

Perhaps the most important reason for this attitude lies inherent in the nature of the disease. Adult tuberculosis, as it is seen in this county, usually begins insidiously and the patient does not feel ill enough to consult a doctor, or, if a doctor is consulted, the patient is unwilling to consider his disease, apparently minor in nature, seriously. This has been said in various ways many times before. But after all it seems to be the one outstanding factor causing delayed diagnosis and poor

cooperation early in the course of treatment. Conversely a brisk hemorrhage, a pleurisy pain or hoarseness serves as an asset to the doctor who is urging bed rest.

In cases of mild onset, the physician first diagnosing the condition has a solemn duty to perform, and his opportunity once lost may not be grasped again by him or any other physician until too late. At the risk of losing his patient, it is urgent that the seriousness of active pulmonary tuberculosis of whatever stage be impressed upon the patient. To be sure, certain patients will resent this frankness and will consult other doctors, possibly continuing to change doctors until a verdict is rendered which pleases them, but a physician can well afford to lose such patients. Experience warrants the view that frankness is abundantly justified. Phthisiophobia in diagnosed cases, has not been, in the writer's experience, a bugbear, provided the physician-patient relationship has been one of frankness and confidence. An early conference with responsible family members in which a detailed program is outlined, may be advisable, unless the case is at once turned over to the official tuberculosis authorities for instruction and treatment. Prompt decisive action will keep some patients from resorting to chiropractors and will save a fair number from untimely death. Confidence breeds confidence, confidence cooperation.

Late consultation is due sometimes to the knowledge that tuberculosis has not been found in the family previously, and, on the contrary, sometimes to fear that it may be found and that the patient will thus be branded for life. A good many older people take pride in the fact that they have never needed a physician and this sometimes results in a late diagnosis. Occasionally a Christian Scientist comes to a tuberculosis death with a late ante-mortem or a postmortem diagnosis.

Financial considerations prevent many from curing as they should, although in New York State the provisions for free institutional care, and for the assistance of the family, are good. If health insurance or sickness benefits should become available to those whose income is too low to cover medical care, patients would no doubt submit more willingly, and with fewer financial worries, to a long period of treatment.

In what has been said no attempt has been made to deal with the patient and the family separately. Frequently noncooperation is a family and not an individual problem. In these instances the doctor needs to meet and overcome the combined resistance of family members. Sometimes a sensible nurse can help.

Some of the reasons experienced in this county for delay in diagnosis and for poor cooperation in treatment have been mentioned. Other reasons might be listed. As a rule they are found to be based upon misinformation regarding the nature of tuberculosis. Occasionally a patient, knowing essential facts, deliberately chooses a "normal life" even though it be certain to be a short one, in preference to a longer life which involves a period of cure. These instances, fortunately, are uncommon. The more hopeful and the more common type of patient is the one who lacks accurate information but whose mind is open to instruction leading to cooperative action.

In this process of instructing, the family physician's important part has already been stressed. After he has found or helped find a few cases he will be on the look-out for other suspected cases which he will want cleared up. He can be a great asset to the official agency in persuading a patient to undergo a long course of treatment and in seeing that the entire family is properly examined and protected, while the health agency often can be of assistance to the physician by providing expert diagnostic service without expense to the patient.

As for moulding the psychology of the future generation in health matters, it would seem that the very early education of children in proper social attitudes with practical lessons in cooperation with movements or organizations for the benefit of the community might be worth while. It would seem that in high school a few fundamentals regarding the transmission and the means of early diagnosis of tuberculosis could be taught. In this connection, the x-raying of high school students, while it may reveal little significant tuberculosis, has educational value, as it makes it more likely that students examined in this way will in the future submit to or even seek an x-ray examination should it seem desirable.

GALL-STONES IN THE APPENDIX

F J LENNON, M D, *Buffalo*

Gall-stones have been found in the appendix at operation on a few occasions, but the condition is so rare that in a review of the literature only three articles¹⁻³ were found dealing with this subject

The case I am reporting is of interest in that at no time did the patient have any evidence of biliary tract disease, had never been jaundiced, never had any gastric complaints or change in bowel function

He was twenty-seven years of age, of splendid physique, and never seriously ill in his life. He stated that three days before consulting me he had attended an outing at which he had eaten a large quantity of sausage and sauerkraut and consumed a considerable amount of beer. The following morning he felt somewhat sick but did not vomit. He consulted his family physician who prescribed some medicine, presumably for his gastric distress. This was followed by a bottle of magnesium citrate which produced a watery stool.

He walked into my office without assistance and did not appear to be particularly ill. His temperature was 97 and his pulse 80. He was definitely tender in the right lower quadrant and also in the epigastric region. I prevailed upon him to enter the hospital where a blood count revealed 11,000 white blood cells.

I felt that an operation was indicated in view of his continued nausea and the white count, and entered the abdomen by a right rectus incision to have sufficient space for exploration. Immediately there was presented an enormous mass which had the appearance of a large sausage. I did not recognize it as the appendix at first because of its size and appearance. Considerable fluid was found in the peritoneal cavity but no pus, and after I had satisfied myself that this mass was the appendix, the utmost difficulty was experienced in delivering it as it was gangrenous from tip to base and

bound to the pelvic wall by adhesions. It was removed without being opened and the patient made an uneventful recovery. He was discharged from the hospital on the ninth day.

The appendix was submitted to the pathologist who reported as follows:

Gross examination shows it to measure 8 x 2.3 cm. There is a very marked congestion of the superficial blood vessels. Situated in the organ are three large stones, one in the proximal end near its attachment to the cecum, one in the center, and one in the tip. In each of these enlarges is a gall-stone. The one in the proximal is smooth, round and measures 1.5 cm. in the diameter. The central one is nodular and sharp, and measures .7 cm. in diameter. The third one is black triangular and measures .5 cm. in diameter. The appendiceal wall is much thickened.

Microscopic sections show thruout the thickened wall a moderate infiltration with pus cells, which appear to be uniformly distributed thruout the wall. The serosa is much thickened and contains congested blood vessels and a moderate infiltration with pus cells.

Conclusions

It is remarkable that gall-stones of the size found in this appendix could pass through the common duct without pain. It is generally assumed that the passage of gall-stones will be revealed by cramp-like or colicky pain in the right upper quadrant, and particularly at the moment that they pass into the duodenum.

The further interesting point is that at no time either before operation or since (over one year) has he had the slightest evidence of cholecystitis or jaundice.

Dr Alfred Salter, a medical member of the British House of Commons, recently called the attention of the Commons to the danger of automobile drivers taking any alcoholic drink whatever. Dr Salter said that all agreed that the intoxicated driver should be severely dealt with, but there was a greater danger of the subintoxicated—the man who was not drunk in the legal sense but was physiologically under the influence

of alcohol. A committee of the British Medical Association came to the conclusion that there was serious objections to the consumption of alcohol in quite small amounts by any one who had to drive a car. At least twenty-five per cent of road accidents were due to the fact that the drivers had consumed small quantities of alcohol. They were not intoxicated but, as the British Medical Association said, subintoxicated.

HORMONAL CONTROL OF THE UTERUS

RAPHAEL KURZROK, M D, Ph D, EDGAR G MILLER, Ph D,
JESSIE REED COCKRILL, M D, *New York City*

From the Department of Obstetrics and Gynecology, the Department of Biochemistry, and the Sloane Hospital for Women, the College of Physicians and Surgeons, Columbia University

Motility of the uterus depends on three factors, namely, those inherent within *smooth muscle* itself, autonomic nervous control both extrinsic and intrinsic, and control through chemical substances circulating in the blood, especially hormones. These factors are not of equal importance. There may exist special variations as to which plays the most important and controlling role.

The uterus is an involuntary, unstriated muscle. It possesses the spontaneous rhythmic activity common to all such muscle. Like all hollow viscera it adapts itself to its contents, maintaining at all times a distinct tonus. It can be distended, thus increasing the tension within the organ. The contractions resulting from the introduction of a foreign body into the uterine cavity may not be the same as the spontaneous contractions of the uterus at rest. This is of importance, especially in view of the recent attempts to study uterine motility by means of a hydrostatic intrauterine bag. It is questionable whether such contractions exemplify the spontaneous movements that occur in the uterus. They may merely present expulsive efforts on the part of that organ to rid itself of a foreign body. There is ordinarily very little space between the uterine walls, and the introduction of a bag results in the formation of a distinct *cavum uteri*.

Studies of uterine motility have therebeen made both *in vivo* and *in vitro*. Knaus, Reynolds, Allen, and Corner have worked chiefly with the rabbit, while Robson, Moir, Knaus, and ourselves have utilized the human uterus. Knaus, Moir, and recently Watson, Wiesbader, Kurzrok, and Mulinos have studied the contractions of the human uterus *in vivo* by means of an elastic intrauterine bag. We have recently reported observations on muscle strips from more than five hundred human uteri studied *in vitro*. It might be argued that the uterine strip is

also not a true indicator of the contractions that go on in the human uterus *in situ*. The strip is severed of all nervous control. It is true that in the body the uterus is subject to both motor and inhibitory nervous influences. But, at the same time, facts have accumulated showing independence of this nervous control. Thus, in the rabbit, Rein¹ (1902) reported the spontaneous birth of young following section of all extrinsic nerves to the uterus, while Kammerster and Reynolds² recently demonstrated that the transplanted uterus is subject to hormonal control and the innervation is non-essential. Cannon et al.³ reported spontaneous parturition in cats and dogs following complete extirpation of the sympathetic trunks. J. Novak⁴ in discussing the effect of lesions of the central and peripheral nervous systems quotes numerous clinical cases from the literature showing that even very extensive lesions may have no effect on ovulation, pregnancy or labor. Parturition following complete paralysis of the lower half of the body by reason of lesions or transection of the spinal cord, proceeds very frequently with abnormal rapidity. It is our belief that the reactions of the human uterus observed both *in vitro* and *in vivo* give similar results, so that even though there are objections to either method alone, the combination of both gives us a fair understanding of some factors controlling uterine motility.

Study of the hormonal control of the rabbit uterus has yielded interesting facts which aid in our understanding of the human uterus. When these are compared with the results of study of the human uterus, however, it becomes obvious that one must be cautious in applying to one species the conclusions obtained with a different species. Some of the important results with the rabbit uterus may be summarized as follows.

In vivo experiments have shown that

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 28, 1936*

oestrin is necessary for the initiation and maintenance of rhythmic motility of the normal rabbit uterus.⁵ The rabbit uterus is refractory to pituitrin when under the influence of a functioning corpus luteum (in pregnancy or pseudopregnancy).⁶ Crude corpus luteum extracts⁷ and crystalline progesterone⁸ inhibit the estrus mobility and reaction to pituitrin. Production of a pregestational endometrium

as natural and synthetic progesterone injected into a rabbit castrated during estrus (18 to 20 hours after mating) brings about inhibition of the reaction of the rabbit's uterus to pituitrin.⁹

During pregnancy, pituitrin produces no effect upon the uterus during the early stages, but an increasingly stronger effect as the period of labor approaches. Several days following parturition the reac-

Fig. 1 Spontaneous contractions of the human uterine strips *in vitro*. E. M., sixth day of cycle, G. P., guinea pig uterus during estrus, E. F., at end of six weeks bleeding. Note spontaneous change of rhythm and character of contractions, M. S., early in cycle (before tenth day), E. S., early pregnancy (fortieth day). It is expected that the corpus luteum of pregnancy would inhibit such contractions, M. R., during menstrual period, F. W., twenty-fifth day of cycle, E. B., twenty-fifth day of cycle, J. S., twenty-first day of cycle.

and inhibition, *in vivo*, of estrous mobility are both caused by progesterone. Oestrin added to the perfusion bath in any concentration will not initiate spontaneous rhythmic motility in a quiescent uterus. This may be due to the slight solubility of oestrin in water. Castration produces a loss of spontaneous uterine contractions and a lack of response to pituitrin. Oestrin injected into a previously castrated rabbit re-establishes the uterine response to pituitrin. Corpus luteum hormone added to the perfusion fluid is without effect, probably because of its limited solubility. Impure corpus luteum extracts, as well

as natural and synthetic progesterone injected into a rabbit castrated during estrus (18 to 20 hours after mating) brings about inhibition of the reaction of the rabbit's uterus to pituitrin.⁹

The *in vitro* tests of human non-pregnant uteri that we have recently reported¹¹ have given results which do not consistently parallel those obtained with the rabbit. A review of these may be of some interest.

Before we subject the human uterine strip to the action of any chemical substance, it is essential to determine whether the strip is "alive" or not, that is, whether it shows spontaneous contractions. Strips that fail to show spontaneous contractions

at the end of one hour in the perfusion fluid (Ringer's solution) are discarded. Why some strips will not show any spontaneous contractions is, at present, unknown to us. It does *not depend* upon the phase of the uterine cycle. It may be due to excessive handling at time of operation or to the anesthesia (gas-oxygen and ether in almost all cases). As a rule adjacent muscle strips show a similar activity or lack of activity. The activity does not depend upon the length of time (up to perhaps 12 hours) the uterus has remained outside of the body

should be accepted as pharmacological reactions.

The action of crystalline oestrin or progesterin on the uterine strip has not as yet been fully studied. The reaction is limited because both oestrin and progesterone are insoluble in Ringer's solution, and the addition of a solvent greatly modified the activity of the strip.

Since the phase of the cycle when the strip is removed was known in our studies, through the menstrual history of the patient, the histology of the ovaries and the endometrium, it was possible to

Fig 2 Number of uteri examined during various days of a regular menstrual cycle. None were obtained during the second, third, fourth, and fifth days of menstruation, we usually do not operate during menstrual flow.

Nor does the failure to exhibit spontaneous contractions depend on any demonstrable pathology within the uterus. Only uteri free from such lesions were used, except for a few which showed one or two *small* fibroids. Only uteri within the child-bearing age were utilized.

The spontaneous rhythmic motility of the uterine strip varies considerably. There are variations of tempo, rhythm, and extent of contractions in the different strips (Fig 1). Parallel strips from the same uterus behave similarly. When two strips from different uteri are set up in the same chamber, each one maintains its own type of spontaneous motility independently of the other. The reasons for these variations are unknown. They are independent of the menstrual phase during which the uteri are removed. Nor are they functions of the various muscle coats. In our present state of knowledge we are not justified in reading into these variations any special significance. Furthermore, one must be careful in the interpretations of the results obtained when various substances are added to the perfusion fluid. Minor variations in the course of the graph are without significance for they may occur spontaneously. Only definite and unmistakable changes

observe the reactions of the human uterine strip during the various phases of the menstrual cycle. The uterus showed spontaneous activity during all phases of the cycle (Fig 2). There was no inhibition of spontaneous motility during the corpus luteum phase, the uterus reacted to pituitrin during all phases of the cycle. In those cases (9 per cent of the series) in which the uterus did not react to pituitrin it was apparently not due to corpus luteum inhibition, for cases occurring, for example, on the eighth and ninth day of the cycle showed a typical postmenstrual endometrium.

From these facts we may conclude that the human uterine strip exhibits spontaneous uterine contractions, and reacts to pituitrin during all phases of the menstrual cycle. There is no corpus luteum inhibition. These observations do not support the contention of Knaus that during the corpus luteum phase the uterine motility is suppressed and the reaction to pituitrin absent. Hence, no conclusions can be drawn as to the time of ovulation from the reversal of the uterine reaction to pituitrin (contraction before ovulation, and no reaction after it).

We are indebted to Prof Benjamin P. Watson for constant encouragement and

advice, and for placing the large material of the Sloane Hospital for Women and the Vanderbilt Clinic at our disposal. We also wish to thank Prof. Charles C. Lieb and Michael G. Mulinos of the Department of

Pharmacology for their kind advice and assistance in both the technique and the interpretation of these results.

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B. LIBER, M.D., DR.PH., New York City

Editorial Note Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine

Torture

Homosexuality is one of the conditions often intimately connected with mental maladjustment. Not necessarily so, as there are many addicts to this sexual irregularity who are quite happy and contented with it and with the world. But where there is a strong inhibition a conflict results which has a detrimental effect upon the mind.

Of course, there are congenital and partly congenital homosexual individuals, but the majority of those suffering from or enjoying this aberration have acquired it, in spite of what a Magnus-Hirschfeld and other authorities might say. And in its acquired form it may be either the effect or the cause of an abnormal state akin to a psychosis. Some intellectuals and highbrow people like to coquette with it and find ready imitators among their half-baked admirers. But immense harm has been done in this way to many youths of both sexes who, if left alone, would have been plain, happy individuals, engaging in normal heterosexual life and sane thinking. Homosexuality is also spread in the so-called underworld, that is among prostitutes and their parasites, among people with low grade mentalities and among the decaying European feudal nobility and the money aristocracy in Europe and America. It is much less known to workers, whose sex life is, as a whole, cleaner and simpler than that of other social strata.

The conflict may be due either to the struggle to liberate oneself from the clutches of this habit or necessity, to a desire to be like everybody else and have a heterosexual mate, or to an ungratified yearning for homosexual relations.

The following case belongs to the latter group.

A girl is brought by her sister who is unaware of the real trouble. There are the usual complaints which baffle the family—those resembling indigestion.

The patient is "wasting away, doesn't sleep or eat." In reality she is suffering from the effects of an internal fight against the influence and impact of a strong and corrupting feminine personality, whom she has never seen, but whose acquaintance, by mail, she owes to a common friend. She wishes, but is afraid and ashamed, to submit.

The letters she receives, she says, are frightfully wearing and upsetting. They make her weak, limp and "feverish." They drag her "down and down." She is asking her correspondent faintly to cease writing, but the latter keeps blithely on as before—and our patient does not really do anything to stop her, because she secretly enjoys these love messages.

Letter after letter speaks of day-dreams about our patient, suggestive "big kisses wherever you like them most", of "oral intercourse", of "playing with myself" in front of patient's photograph, of being "in each other's arms" and of other, unprintable situations. One missive contains these sentences: "When I saw your letter my heart beat wildly, my breasts and nipples stiffened and little hot quivers ran up and down my thighs. My mind and body flamed. Do say that you understand, please, do, darling! Don't suppress your desire. You are beautiful and you have the most passionate, sensual mouth that I have ever seen."

The only way to tear the patient away from the temptation to go and meet her correspondent, the only possibility to free her from her mental torture was to show her how insincere her so-called friend was. The copious letters brought to the doctor betrayed their author, proved that this "lover" was a professional depraver of girls, that she had made other victims and, moreover, that she could not be a true "homo", as she also described her love of the male sex and her thrill at the contact with men. She wrote, for instance, about the glorious night with a young man "Cocktails, dinner, dancing, highballs no end and then, he kissed so divinely, his hot, wet lips, his hands, my fingers trembling, unfolding, caressing, squeezing, engulfing. He is such a large man. Simply huge." Then, speaking about another man "He asked me to go out with him and I accepted. I know I shouldn't, but I just cannot help it. I am sure he is aware of my desires. He is quite sophisticated and he must have noticed my lowered glances. He is so virile and athletic looking. That is so utterly visible."

I purposely fail to mention other passages. No true homosexual can write that way unless there is a studied intention to provoke and attract a person in order to reap some advantage later.

A street car motorman had had trouble with his young wife. She suffered from an attack of mental depression soon after the birth of her first child. He had to place her in a State hospital for the insane and the baby in an orphan house. Meanwhile he broke down himself. He was fidgety, sleepless, given to crying and long fits of distraction. He was "neither healthy nor sick," he said. But his condition became particularly bad when his job was changed from plain motoring to the combination of driver and conductor. He must drive, that is pay attention to his handles, to the road, to the other vehicles, to pedestrians, to lights, to stops, to starts, he must look at the hind door of his car, open and close it, let the passengers in and out through the front door, answer their questions, give them change, see that they pay fare.

Efficiency

This patient was a German and he said "I am like a *Neapolitanischer Dudelsackpfeifer*, who makes music using his hands, his feet, mouth, head, *und so weiter*."

He was unable to work, but wanted to keep his job. So I had to give him a letter to the company, his employer, worded in such a manner that his mental state should not be suspected, as that might have been misinterpreted and might have resulted in his being sent away permanently.

A vacation proved to be a blessing. But he himself could not return to his occupation, which he tried to do three times, unsuccessfully. There was too much "efficiency" for him.

Another work, this time in the car barns, was tolerable. But his real cure came only after he acquired a new sweetheart and he half forgot his wife.

THE RIGHT WORD AT THE RIGHT TIME

There are scare-words which, when carelessly applied to a patient, make him anxious and apprehensive. And there are comfort-words, expressions which, coming from a trusted physician, banish fear. By use of these symbols the nervous system can be

played upon as though an instrument. The charlatan employs them to establish conditions which he can capitalize for his own profit. The wise doctor knows how to use them as a part of his therapy.—*Annals of Internal Medicine*

Privilege and Duty

Only a few weeks remain for physicians to organize their political strength for effective action at the polls. After November third the officials elected to executive and legislative positions will be able to exercise great power over the practice of medicine. Now it is in the power of the medical profession to help determine who the successful candidates shall be.

The widespread interest displayed in the coming elections is a healthful sign of the vitality of democracy in this country. More than almost any other group the medical profession has a heavy stake in the outcome. Every citizen desires to see the party representing his political convictions elected. In the case of the physician, it may well be that professional independence and economic opportunity hang in the balance in the present campaign.

The election of a preponderance of candidates committed to compulsory health insurance, chiropractic or other fallacious theories would lower medical standards, weaken professional responsibility, and destroy the economic incentive to graduate study and individual research. Physicians must do their utmost to prevent such a political set-up.

Observers have frequently commented

on the large number of doctors who fail to utilize their vote. This is a sad reflection on both the civic consciousness and political realism of the delinquent practitioners. Any group which turns its back upon the ballot box should not be surprised if those elected by the ballot are indifferent to or trample upon its interests. As citizens physicians have an inescapable duty to vote. As practitioners of a profession under strong political pressure, they cannot afford not to do so.

Physicians with any professional vision will recognize that their duty—and opportunity—do not end with ascertaining the views of candidates and casting an enlightened vote. The practitioner with an eye to the public welfare—and his own—will carry the campaign to his patients and lay friends in order to organize and bring into action all the forces opposed to political and professional charlatanry.

News for Doctors

In the quarterly survey conducted by *Fortune*,¹ an extremely interesting bit of information is revealed. It is probably the first time that the public has been

¹ *Fortune*. The Fortune Quarterly Survey p 211
222 September 1936

approached to determine its attitude toward health insurance and socialized medicine. A group representative of the cross-section of our population was asked whether or not they would be willing to spend ten dollars a year to insure against possible hospital expenses. An affirmative answer was obtained from 47.9% and a negative response from 44.3%. The remainder were undecided.

Fifty-eight per cent of those questioned spent less than twenty-five dollars per annum for all medical expenses, yet this group comprised 50.8% of all those favoring the hospital plan. *Fortune* concludes from this that "for both dental and medical health insurance at ten dollars per person there would be wide acceptance." However, they overlook the fact that under the Associated Hospital Service plan which they have taken as the criterion for their question, the physicians' fee is not included in the premium. To cover this phase of health insurance would more than double the necessary outlay for each insured so that the largest proportion of the population who pay less than twenty-five dollars a year for medical care would have this figure increased.

In addition to the above statistics, seventy-four per cent were in favor of providing medical and dental care at the expense of the taxpayer for those who could not pay. Under our present system of medicine this already exists. In the large cities, free medical care is provided by direct taxation and maintenance of hospitals and health agencies. In the rural districts, the various counties have the Poor Commission which takes care of the indigent.

Any modification of our system of medical care can be made within the framework of that system as it exists today. It is not necessary to foist upon the American people types of medical practice that have, in other countries, proven inadequate. It is only active education by the medical profession that can overcome subversive propaganda.

The sooner the medical profession assumes its proper place and goes before the public, the quicker will the erroneous conception of the value of socialized medicine and health insurance be dispelled from the public mind.

A Timely Warning

The advice given by James O. Hoyle, Investigator of the State Department of Education, to the New York State Shoe Retailers Association should not be resented or ignored. In recent years there has been a growing tendency on the part of shoe salesmen to usurp titles and prerogatives which properly belong to physicians and podiatrists. Not satisfied with skill in their own trade, they are representing themselves as "foot experts." In addition to style, comfort, and durability, curative virtues are implied to reside in ordinary shoes by trademarking them with a quasi-medical name.

Such practices not only are improper and detrimental to the public health, but actually infringe the law at certain points. Many dealers are unaware of the impropriety or illegality of acts committed in common with large numbers of their competitors. Mr. Hoyle has rendered a service to the shoe industry by clarifying the statutes and defining possible infractions.

In a nation long past the barefoot stage, misrepresentation is not required to sell shoes. Beauty, durability, and comfort are all the selling points a good shoe needs. An intelligent manufacturer will attempt to make his shoes conform to the anatomical structure of the human foot. This does not justify distributors in attempting to diagnose foot ailments or cure real or imagined deformities in individuals by the prescription of shoes manufactured in the mass.

The State Department of Education has done well to go directly to the shoe industry with an explanation of the law and possible unintentional violations. The next step is strict and unrelenting enforcement.

Ozena

The exact etiology of true ozena is still unknown. Many theories have been advanced to explain its pathogenesis but none has been accepted as fully accounting for both the clinical and microscopic picture presented by this disease. In addition to the progressive atrophic change noted in the upper respiratory tract, the abnormal width of the nasal chambers which results, leads to the development of extensive crusting and offensive odor.

It is this latter symptom which leads to social ostracism of the patient and makes an introvert of him. Fortunately, however, the clinical manifestations of ozena, both the odor and the crusting, can be corrected permanently by surgical means. Based upon the assumption that the side nasal cavities plus the alteration in intranasal air currents are the responsible factors in causing excessive drying of the mucus with the formation of four smelling crusts, Lautenschlager,¹ Pollock,² Wachsberger,³ and others have devised operative means of narrowing the internal nares. By these measures the cause of the crusting is eradicated even though the underlying pathological process remains unaffected. All odor disappears and the patient no longer is compelled to shun his fellow men.

CURRENT COMMENT

"NOTED REICH DOCTOR WARNS NAZIS ON Science, Declares Their Tampering Might Wreck It" states the caption heading an article in *The New York Times* of September 23. "Dr Ferdinand Sauerbruch, noted German surgeon, issued today a warning to the political regime to let science alone unless it wants to wreck it. At the same time he warned the nation's National Socialist youth that it had better get along without an ideology for the time being and wait until it was mature enough to form opinions about fundamental questions * * *

¹ Lautenschlager, A. *Die Rhinitis atrophicans* in Denker A. and Kahler O. *Handbuch der Hals Nasen u. Ohrenheilkunde*, Julius Springer Berlin, 2 604 1926

² Pollock, H. L. *Ann Otol Rhin & Laryng* 36 241 1927

³ Wachsberger, A. *Arch of Otolaryng* 19 370 1934

'Science does not need any scrubbing by outsiders. Science has always been the greatest of revolutionaries and has freed itself from weaknesses and mistakes. Science must remain true to itself * * * Science will fulfill what is demanded of it on condition that it retain its freedom and independence in its work. In spite of all necessary limitations, liberty remains an essential characteristic of science, and spiritual and intellectual freedom is a necessity for scientists. Every true scientist desires to serve his nation. His work, however, cannot be complete if it is merely a service to the nation. His research is not alone a creation of this immediate world, but it is closely related to eternal questions * * *

'Full and complete understanding of the world is a result of long labor and hard experience. This experience must be repeatedly tested by the intellect. An ideology is something that only matured and tried men and women can earn for themselves. Ideology is no affair of youth, which has instead strength, ambition, faith, and hope. These characteristics of youth degenerate, however, if it does not seek knowledge and understanding.'

"UNDOUBTEDLY DR. FERDINAND SAUERBRUCH had the support of the majority of his auditors when he told the German Medical Congress on Monday that spiritual and intellectual freedom is essential to the development of science, at the same time boldly warning the Government that the work of the scientist can never be complete if it is merely a service to the nation. This is the corollary to the thoughtful address of Sir Josiah Stamp a fortnight ago before the British Association for the Advancement of Science"—The foregoing is from an editorial in *The New York Times* of September 27, 1936 on *Science and the State*.

The editorial continues " * * * Sir Josiah's thesis was not the duty of the State to leave the scientist free. On the contrary he discussed the duty of science to guide the State and shape the social system. It is obvious, he said in effect—and in this he is echoed by the German surgeon—that science is the greatest of revolutionaries. Science does not work and develop in a vacuum, its inventions and discoveries cause profound social changes. The new question he raised is not one of restriction—like the 'ten-year moratorium' to enable society to catch up with invention—but of the obligation of science to apply the scientific method to the study of its impact on society. Is it time for science to plan a 'change absorber' to cushion the shocks and disturbances it brings about? * * *

"The social cost of scientific change is the subject of much conversation but little scientific study. A kind of twilight zone, similar to the no man's land between the functions of the State and the Federal Government, lies between workers in the field of science as such and workers in the field of sociology. Yet in this twilight zone stalk many of the crucial problems of our time. To talk of planned economy, as Sir Josiah Stamp points out, without a continual technical study of the chief factors that set the pace of change, without a 'balanced dosage' of science, is to tangle up progress in crisis after crisis. All that he says implies just the opposite of the claims of the totalitarians: the State dare not curb science, but science—the expanding knowledge of the facts of life—must guide and direct the political institutions through which human society functions."

"* * * THE SOCIAL SECURITY ACT heaps responsibility on an already overloaded profession. And it's the kind of responsibility that cannot be dodged. Intelligent physicians, acting both individually and through their societies, have injected themselves into the program instead of standing by and clucking dismay at the damage it may do them. Maternal welfare, public health, and medical economics committees are cooperating with state agencies that control the services to be rendered under the Act. They have placed themselves in a position at least to curb, if not prevent, undesirable outcomes. What is your society doing about it—and you?"—*Medical Economics*, September, 1936

AN ADMONISHMENT WELL WORTH QUOTING is contained in the *St. Louis County Medical Society Bulletin* of September 18, 1936, to wit: "Every once in a while we read in the newspapers of somebody lifting the entire thought of an article and using it as their own brain child, to their own confusion and embarrassment when it becomes known later that they did not actually write the article or story. * * * We are afraid that some of our good medical editors do not observe enough care in their clipping from other medical bulletins. They fail to give credit to the original publication or author and print the article as though it were their own. This is probably done because of either ignorance or of carelessness, but it should not happen. * * *

"When I read my article in some other bulletin without any credit or even 'exchange' at the close of the article, I immediately question every other article in that

publication. If all of the other editors see the article in our bulletin and a month later see it in some other bulletin without distinguishing mark of authorship, they also feel some doubt as to all other articles in the publication. Let all editors of *Medical Society Bulletins* be more careful in giving complete credit to all articles from other publications, so that no stigma may be cast upon any of our editors. It is a good habit and may save very much embarrassment sometime."

"* * * INCIDENTALLY, WHATEVER MAY BE ARGUED against the League of Nations, it may be said that its existence has been justified by the splendid work done by those in its service in preventing disease."—An opinion voiced by the editors in *Medical Record* of September 16

"THERE WILL ALWAYS BE PITY for those whom floods pursue, and callousness, in the long run, for the victims of misfortune man makes for himself. Yet only mankind can destroy mankind. Floods will not be man's mortal fate"—Dorothy Thompson in the *New York Herald Tribune*.—The quotation is taken from the columns of the September issue of *The Survey*. The following selection is from the same source: "Man incessantly seeks to compromise with his conscience or with his innate humanitarianism, by rationalizing his predatory behavior."

He insists upon playing the game, not only with an ace up his sleeve, but with the smug conviction that God has put it there.—Prof. Earnest A. Hooton, Harvard University * * *

"* * * ADVOCATES OF STATE MEDICINE have wept long and bitterly over the death rate among industrial workers (the group to which their theories chiefly apply). They have held up the 'shocking facts' as proof conclusive of need for change. But recently the lie was thrown squarely in their teeth."

"The Metropolitan Life Insurance Company handles a large proportion of the industrial insurance of the nation—insurance purchased by the same class of citizens who propagandists would lead us to believe are dying like flies because of lack of medical attention."

"Contrasting the health of the 17,000,000 industrial policyholders during the first half of 1936 with that of the general population, statisticians of the company report that deaths among the insured group came within one-fourth of one per cent of the all time low established during the first six months

of 1935, while the mortality record of industrial employees as a whole is substantially better than that of the rest of the population

"This is something to think about, for from the U S Bureau of the Census comes the disclosure that the average span of life is a decade longer today than it was at the turn of the century. This progress, the

Bureau states, is due largely to advances made in the science and practice of medicine and surgery

"When national health is at its best and when our health standards are the envy of the world, crying propagandists take on a strange resemblance to crying crocodiles"—William Alan Richardson in the September issue of *Medical Economics*

TAKING THE X OUT OF X RAY

The "x" in x-ray was put there because the ray was an unknown quantity, and even now, when we think we know pretty much all about it, its dangers are directly due to what the people who handle it don't know. The layman who tries to make x-ray examinations may be a good technician, but he is not a medical man, and is not qualified to interpret the pictures he takes. Equally, too, the doctor who owns an x-ray machine may have the highest medical skill, but may lack a thorough knowledge of his apparatus, unwittingly injure his patient, and let himself in for a heavy damage suit. So there are still several "x's" in this mysterious ray.

An interesting article from the Special Committee of Radiology, in *The New York Medical Week*, says that "the Committee feels that roentgenology is a form of medical practice," and goes on

The layman does not have the adequate training necessary to do this type of practice safely and efficiently. X-ray diagnosis involves far more than photography. A thorough knowledge of pathology and manifestation of disease is essential. Only a medical training can give this. The physician who refers his x-ray cases to laymen bears a heavy responsibility to the profession at large, the future efficiency of the radiologist and, above all, the welfare of the patient.

The Committee is also of the opinion that those physicians who use x-ray apparatus should have sufficient knowledge to operate and keep such machines in a manner to insure the maximum safety to the patient. There are undoubtedly many installations now in operation which are potentially dangerous but could be corrected by minor adjustments.

The harmful effects of inefficient x-ray work divide themselves into two general groups: diagnosis and therapy. In diagnosis, there is always the danger of severe electrical shock or death in open installations, that is, where the high-tension wires are exposed. The installing of shock-proof equipment will, of course, considerably reduce this danger but not entirely eliminate it. There is also the possibility of giving an overdose of x-ray with the production of an x-ray dermatitis. An x-ray dermatitis in diagnostic work almost invariably results in a heavy law suit. The dangers of unskilled application of therapeutic x-rays are even greater. Serious and permanent damage and even death may result from unskilled therapy. This is well

illustrated in the terrible disfiguring end results of epilation by x-ray as carried out in certain beauty parlors. The resulting after effects are not only disfiguring but a particularly vicious form of carcinoma is apt to occur at the site of the dermatitis.

The Editor of *The New York Medical Week* reinforces this report with a thoughtful editorial, remarking

Patients requiring radiological service run a more than average risk unless they fall into expert, conscientious hands. Poor equipment adds to the dangers of mediocre or insufficient training. The good craftsman in every field employs fine tools and keeps them in order. So the qualified specialist in Roentgenology almost always has the best machines, with maximum safety devices. In commercial laboratories run by lay technicians, on the other hand, cheap installations are common, inspection infrequent. The operators either do not know or are indifferent to the dangers to which faulty apparatus subjects the patient.

If radiology consisted solely of photography there would be some excuse for the independently practicing technician. Accurate x-ray diagnosis demands a thorough understanding of pathology and its radiographic manifestations, however—knowledge that is supplied only by medical training.

The possession of a doctor's degree does not qualify a physician to practice radiology without further preparation. In addition to his general medical education he must understand the nature and effects of the Roentgen ray and the structure (with its attendant hazards) of the x-ray apparatus. Over and above all this there must be skill in the operation of the machine, ability to interpret fine details on the plate and judgment in the application of therapeutic dosage. If the average physician is not ready to engage in radiology without special training, how much less so is the lay technician.

The slightly lesser costs of lay service do not compensate for the risks run or the uncertainty of diagnoses made by technicians without professional training. The public does not realize this, however, and the cut rates advertised by many commercial laboratories are a source of destructive competition to the competent specialists who are seeking to advance the science and practice of radiology at the same time that they must earn a living. Practitioners who have occasion to employ x-ray aids to diagnosis or treatment should bear professional standards as well as price in mind and confine their patronage to qualified medical radiologists.

DISTRICT BRANCHES

Fourth District Branch

The thirtieth annual meeting of the Fourth District Branch took place in the State Normal School at Plattsburg, opening Friday October 2, and closing the next day, with an evening dinner session at the Hotel Cumberland on Friday.

The first scientific session opened with a paper on "Treatment of Burns" by Dr Lyman Allen of Burlington, Vt. Dr Allen compared the two most recent treatments by tannic acid and one per cent of aqueous solution of gentian violet, both of which have proven of so much greater value than former methods. He cited experience to show that gentian violet is even better than tannic acid in that it is less toxic, gives greater relief of pain, forms a more flexible covering, and allows earlier skin grafting.

Dr James B Collip of Montreal, described with lantern slides the difficulties of applying newer laboratory research data in endocrinology in clinical work, particularly in the realm of different hormones formed by the pituitary.

Dr Edward K. Cravener of Schenectady discussed the problems of "Hip Joint Disease in Mid-childhood" from the angle of etiology and treatment with lantern demonstration of x-rays and diagrams.

At the dinner session the retiring president of the Branch, Dr John P J Cummins of Ticonderoga first called on the Secretary of the State Society, Dr Peter Irving, to speak on Society activities. Dr Irving stressed the point that these are stirring times for medicine, in this country, when the research impulse is at its highest, yet schemes are in the air that it is feared may not only make delivery of the best in practice more difficult but perhaps choke down research. He described the State Society mechanism as more than usually well-adjusted to meet the challenge.

Dr Lawrence, Executive officer announced that the Department of Education had taken formal action in the matter of licensing foreign physicians in the following terms:

Voted, that on applications filed after October 15, 1936 no license issued by a legally established board of examiners in any foreign country shall be indorsed, pursuant to the provisions of Section 51 of the Education Law, until the applicant shall pass the licensing examination prescribed by law or Regents' rule.

Fifth District Branch

The meeting of the Fifth District Branch convened at the Rome State School on October 1, where four speakers described different phases of the work of caring for the 3600 mentally defective inmates. It was

Dr Floyd S Winslow, President of the State Society, described with pictures some of his actual experience as Coroner's Physician of Rochester, in fatal criminal cases. The presentation indicated the foundation of the crimes in psychoses and other personality disorders, and revealed in most interesting fashion the smallness of clues that led to solution of the problems involved.

Dr John B Wheeler of Burlington, Vt. a graduate of Harvard in 1878, recited reminiscences of his experiences as a surgeon before the days of Lister, when the cause of wound infection was unknown, and the technique practiced led to such a large incidence of wound infection that none dared enter a body cavity of the skull but confined operations to the extremities.

Concluding the meeting on Saturday, Dr Arthur J Norvald of Saranac Lake spoke to the title of "Pulmonary Response to Inhaled Dust." He defined silicosis in part as "a chronic condition of the lung caused by prolonged inhalation of high concentrations of fine silica dust (microscopic particles) producing nodules of fibrous tissue in the walls of the air cells." With slides, he demonstrated the difference between benign pneumoconiosis and destructive silicosis.

Dr Lewis M Hurxthal of Boston read a paper on "Recognition of Early Congestive Heart Failure and Treatment." His presentation was of an informal type but very practical.

Dr George Beilby and Dr John C Mc Clintock of Albany spoke on "Hypertthyroidism in Children."

At the business session of the Branch the following officers were elected for 1937-8: *President*, Carl R. Comstock, M D, Saratoga Springs, *First Vice-President*, Sylvester C Clemans, M D, Gloversville, *Second Vice-President*, Elmer H Ormsby, M D, Amsterdam, *Secretary*, William W Woodruff, M D, Saranac Lake, *Treasurer*, John Edward Free, M D, Ogdensburg.

The Branch went on record formally as in favor of promulgation by the Commissioner of Labor of the same fee schedule for the rest of the state outside of New York City as has already been set for the metropolitan area for Workmen's Compensation.

brought out that with a personnel of only about 600 this difficult and many-sided work has, for long, been carried out in such fashion as to make the most of each individual under care. Marjorie S Brulle, sociol

worker, spoke of the constant need for interpreting to families the handicaps found

Dr Leonora L. Greenman, pediatrician, showed cases exemplifying malnutrition of defective infants and a group of cretins of varying ages. Ralph A. York spoke of the difficulty and uselessness of trying to teach certain of the defectives to read and work, although, because this is a "school" parents expect just that impossibility. Dr Ward W. Willis, clinical director, reported results of long-continued work with certain defectives which has resulted in production of effectual helpers in and out of the institution. He emphasized the fact that these successes were attained not only by careful estimates of capacities but also by the exhibition by those in charge of affection for the individuals.

Wm Robert Dineen, attorney, of Syracuse gave an interesting discourse on causes for malpractice suits.

Dr Irving and Dr Lawrence spoke briefly of the activities of the different committees

of the State Society. Pneumonia control, syphilis control, child welfare, and maternal welfare were described as receiving particular attention. The need for county societies to complete their lists of qualifications of physicians to do compensation work was indicated, the arrangements for arbitration of disputed bills and "lifting" complaints was described. The failure of the Commissioner of Labor, as yet, to promulgate a fee schedule for the state outside of the metropolitan area was voted, and in this connection, the Fifth District Branch went on record as approving the extension of that schedule through the state *without reductions*.

In the afternoon session Dr Donald Guthrie of Sayre, Pa. presented an interesting paper on the present status of "Surgery in Peptic Ulcer," its unwisdom at times and its real need at others. Dr Edwin P. Mayard of Brooklyn gave a paper on "Cardio-Vascular Syphilis."

Seventh District Branch

The thirtieth annual meeting of the Seventh District Branch was held at the Willard State Hospital on September 24, Dr Thomas W. Maloney, president, in the chair. The attendance was about 200.

At the morning session four State Society officials gave addresses. President Winslow spoke to the theme of "Progress of the Society" clearly defining "the doctor's obligation" to provide the public with the best medical care and to protect the public from inferior care. Dr Kaliski, as Director of the Committee on Workmen's Compensation, detailed recent setting up of procedures for arbitration of disputed bills and of "lifting charges." Dr Elliott, chairman of the Committee on Economics discussed the problems of "hospital care" versus "medical care," and the continued opposition to compulsory

health insurance. Secretary Peter Irving indicated that the Secretarial office and the JOURNAL desire closer knowledge of County Society problems.

The scientific papers were begun in the morning and concluded in the afternoon session. Dr Arthur Krida of New York, Chief Orthopedic Surgeon of Bellevue Hospital described surgical procedures and results of operation on knee-joints damaged by arthritis. Dr Edward E. Winkler of Buffalo gave moving pictures of "Miscellaneous Office Procedures in Gynecology" and of the technic of the "Watkins Interposition Operation." Dr W. S. Merle Scott of Rochester pointed out the various points that assist in differentiating malignant from benign ulcerative lesions of the gastrointestinal tract.

DR JIM," HEALER FOR A MILLION ZULUS

"Dr Jim," physician over thirty-five years in Durban, South Africa, has arrived home, says the *Boston Transcript*. In Africa where he founded the first hospital for Zulus in 1899, that is his title. His hospital is "House That Jim Built," and his wife, a trained nurse, is "the Princess." His New England friends who were skeptical when he left here as a young missionary doctor, knew him as Dr James B. McCord of Oakham Mass. "There is only about one

doctor to every million people in Africa," Dr McCord informed us. To meet this great medical need, Dr McCord is training the black to care for his own, as well as relieving sickness and suffering in his hospital. Last year, after a seventeen-year struggle, Dr McCord induced the South African Government to put through a plan whereby young Zulus will receive medical education in the South African Native Colleges.

COMMITTEE ON ECONOMICS

It is announced that to each of the members of the Committee has been assigned the duty of acting as consultant for County Society Committees on Economics in the following areas. In each instance the counties are those nearest to the residence of the consultant.

DR MORRIS MASLON, 191 Glen Street, Glens Falls Tel 2-0026, St Lawrence, Franklin, Clinton, Essex, Hamilton, Warren, Saratoga, Washington

DR CHESTER O DAVISON, Vassar Bros Hosp, Poughkeepsie Tel 24, Kentselaer, Schenectady, Albany, Columbia Dutchess, Greene, Ulster

DR WALTER WESLEY MOTT, White Plains Tel 2072, Putnam, Westchester, Rockland, Orange, Sullivan

DR ALFRED E SHIPLEY, 665 St. Mark's Ave, Brooklyn Tel Sterling 3-2843, Suffolk, Queens, Nassau, Kings

DR GEORGE CLARK VOGT, 140 Chapin St., Binghamton Tel 4-2243, Delaware, Che-

nango, Broome, Tioga, Tompkins, Schuyler, Chemung

DR JOSEPH P GAREN, 140 N 1st St., Olean Tel 5717, Yates, Steuben, Allegany, Cattaraugus

DR JOSEPH C O'GORMAN, 1324 Jefferson Ave, Buffalo Tel Garfield 0139, Orleans, Genesee, Wyoming, Niagara, Erie, Chautauqua.

DR WARREN WOODEN, 39 S Goodman, Rochester Tel Monroe 1804, Wayne, Monroe, Ontario, Livingston

DR FRDERICK STEPHEN, 514 Medical Arts Bldg, Syracuse. Tel 2-1131, Jefferson, Oswego, Onondaga, Madison, Cortland, Cayuga, Seneca

DR CASSIUS HINDS WATSON, 195 B'way, New York City, also Brooklyn. Tel Exchange 3-9800, Bronx, New York, Richmond.

DR F M MILLER, JR., 293 Genesee St., Utica. Tel 2-1814, Lewis, Oneida, Fulton, Montgomery, Schoharie, Otsego

DIAGNOSIS OF FUSOSPIROCHETAL INFECTIONS

Fusospirochetal infections which occur in man are caused by a synergistic group of spirochetes (*Borrelia* and *Treponema*) and fusiform bacilli. In the majority of such infections other organisms such as streptococci, higher bacteria, and vibrios are also present. The lesions, regardless of their location in the body, are characterized by local necrosis, ulceration, and putrid odor. Patients with fusospirochetal infections may have generalized symptoms, slight to very pronounced, due to absorption of toxic products.

There are four locations in the body where this combination of microorganisms is thought to occur under apparently normal conditions: 1 Crypts of tonsils 2 Gingival margins of teeth 3 External genitals 4 Intestinal tract. Thus, any lesion of a mucous surface may contain spirochetes and fusiform bacilli without causal relationship.

Lesions incited by these microorganisms are usually located in or near the above mentioned areas. It is not unusual, however, for remote parts of the body such as the lungs or brain to be affected. Infections of wounds, especially following human bites, are not uncommon.

The following are laboratory aids in diagnosis:

I Tonsil and Throat Lesions (Vincent's angina, ulceromembranous pharyngitis) Swabs may be used to collect material from the ulcerated areas. They should be taken directly to

the laboratory and a dark-field study requested. This is the best method for the identification of the entire flora. It is essential, however, that the material be fresh. If this is not practicable, films should be made on clean slides, allowed to dry in the air, and then sent to the laboratory with a request for the examination desired. Appropriate specimens should also be submitted to exclude the diphtheria bacillus but such a culture is not suitable for examination for organisms of the fusospirochetal group. A differential white-blood-cell count is desirable since similar lesions may be associated with agranulocytic angina or leucemia.

II Trench Mouth or Ulceromembranous Gingivitis Material from the ulcerated areas may be collected on swabs and treated as under I.

III Lung Lesions (bronchial spirochetosis, lung abscess, empyema, or lung gangrene) These conditions may be caused by members of the fusospirochetal group. The sputum, pus, or material from an empyema should be sent immediately to the laboratory for examination.

IV Foul ulcerated lesions in other parts of the body, particularly the genitals or infected wounds resulting from human bites, should be studied for the fusospirochetal group. Capillary pipettes or swabs may be used to collect material for dark-field examination and for slide preparations. Here again it is essential that the material be moist when received at the laboratory.

Laboratory studies are of particular value in these infections because some of them respond readily to immediate and appropriate treatment.—Issued by The New York State Association of Public Health Laboratories, Leaflet No 8

COMMITTEE ON WORKMEN'S COMPENSATION

It has come to the attention of this Committee that certain physicians in the metropolitan area of the State, qualified under the Workmen's Compensation Act, have been requested to treat claimants under the Workmen's Compensation Act without reporting the injury to the Department of Labor as prescribed by the rules and regulations.

Physicians should be careful not to undertake the treatment of a claimant under the Act without making the necessary reports as prescribed by law. Under no circumstances should any physician agree to treat such claimant at the request of an employer without notification. This is a violation of the law, for which all parties concerned will be strictly accountable under the provision of the Labor Law and of the amended Workmen's Compensation Act. Instances of attempts to induce physicians to treat cases without reporting them should be brought to the attention of the Workmen's Compensation Boards of the County Medical Societies at once.

It is again requested that all physicians

pay particular attention to Rule 23 of the rules and regulations promulgated by the Industrial Commissioner covering the amended Workmen's Compensation Law. These rules and regulations are printed in the fee schedule pamphlet. Rule 23 makes it obligatory on the part of a physician superseding another physician in the treatment of a patient, before beginning the treatment of such patient, to make a reasonable effort to communicate with the prior attending physician to ascertain the patient's condition, to advise the prior physician of the name of the patient who wishes his attention, and to give the reasons for the patient's seeking another physician. If the superseding physician cannot contact the prior attending physician after a reasonable time and, if the claimant's condition requires immediate attention, the superseded physician should be advised by the doctor taking over the case within 48 hours, of the above facts.

DAVID J. KALISKI

Chairman

IMPORTANCE OF PRESCRIPTION WRITING

This is stressed in the *Journal of the AMA* by Dr. E. Fullerton Cook. The prescription written for the individual patient, he says, is an important link in a perfected service. An original prescription shows evidence of professional skill and is not a product with which the patient is already familiar through its display in the type of medicine store where no professional knowledge is present and where such standards must necessarily be low. The latter situation is worthy of serious consideration, for the patient is likely to question the justification for a doctor's fee when it results in what may appear to be a "patent medicine" type of treatment. The use of abbreviated official titles written into a prescription and with a "non rep" order controls the situation, while the suggestion to "buy it at the drug store" opens wide the door to self-medication.

Further, the author emphasizes the restriction of routine hospital treatment to official medicines whenever possible. This program for the hospital has within it another possibility of far-reaching significance. It is realized that the medical student has little

opportunity in his crowded curriculum to become familiar with official titles or even to gain practice in prescription writing. This is being recognized by a number of hospitals, and both medical and surgical interns are being given regular training in the use of official medicines and in prescription writing.

The price of a prescription is no small item for consideration in the total cost of medical care. It should be the basis for a complete understanding and must be established on a sound and economically correct foundation. It is proper that the patient should pay for the medicine and that it should not come out of the physician's fee, for that is not economically sound and leads to numerous abuses.

Many physicians today are being persuaded to start the practice of office dispensing. There are conditions in which this is justified, as in a country district where there are no prescription-filling facilities, but that it introduces the possibility of many complications must be conceded, and most physicians return to prescription writing as soon as financial pressure is relieved.

One of the city ambulances of Evanston, Ill. is to be equipped with short wave transmitting and receiving apparatus to enable the ambulance doctor in emergency cases to report the needs of the patient to

the hospital authorities with dispatch. This will permit preparing the operating room before the return of the ambulance or the sending of such other assistance as may be necessary.

Physicians should be careful not to undertake the treatment of a claimant under the Act without making the necessary reports as prescribed by law. Under no circumstances should any physician agree to treat such claimant at the request of an employer without notification. This is a violation of the law, for which all parties concerned will be strictly accountable under the provision of the Labor Law and of the amended Workmen's Compensation Act. Instances of attempts to induce physicians to treat cases without reporting them should be brought to the attention of the Workmen's Compensation Boards of the County Medical Societies at once.

It is again requested that all physicians

pay particular attention to Rule 23 of the rules and regulations promulgated by the Industrial Commissioner covering the amended Workmen's Compensation Law. These rules and regulations are printed in the fee schedule pamphlet. Rule 23 makes it obligatory on the part of a physician superseding another physician in the treatment of a patient, before beginning the treatment of such patient, to make a reasonable effort to communicate with the prior attending physician to ascertain the patient's condition, to advise the prior physician of the name of the patient who wishes his attention, and to give the reasons for the patient's seeking another physician. If the superseding physician cannot contact the prior attending physician after a reasonable time and, if the claimant's condition requires immediate attention, the superseded physician should be advised by the doctor taking over the case within 48 hours, of the above facts.

Chairman

IMPORTANCE OF PRESCRIPTION WRITING

This is stressed in the *Journal of the AMA* by Dr. E. Fullerton Cook. The prescription written for the individual patient, he says, is an important link in a perfected service. An original prescription shows evidence of professional skill and is not a product with which the patient is already familiar through its display in the type of medicine store where no professional knowledge is present and where such standards must necessarily be low. The latter situation is worthy of serious consideration, for the patient is likely to question the justification for a doctor's fee when it results in what may appear to be a "patent medicine" type of treatment. The use of abbreviated official titles written into a prescription and with a "non rep" order controls the situation, while the suggestion to "buy it at the drug store" opens wide the door to self-medication.

Further, the author emphasizes the restriction of routine hospital treatment to official medicines whenever possible. This program for the hospital has within it another possibility of far-reaching significance. It is realized that the medical student has little

opportunity in his crowded curriculum to become familiar with official titles or even to gain practice in prescription writing. This is being recognized by a number of hospitals, and both medical and surgical interns are being given regular training in the use of official medicines and in prescription writing.

The price of a prescription is no small item for consideration in the total cost of medical care. It should be the basis for a complete understanding and must be established on a sound and economically correct foundation. It is proper that the patient should pay for the medicine and that it should not come out of the physician's fee, for that is not economically sound and leads to numerous abuses.

Many physicians today are being persuaded to start the practice of office dispensing. There are conditions in which this is justified, as in a country district where there are no prescription-filling facilities, but that it introduces the possibility of many complications must be conceded, and most physicians return to prescription writing as soon as financial pressure is relieved.

One of the city ambulances of Evanston, Ill. is to be equipped with short wave transmitting and receiving apparatus to enable the ambulance doctor in emergency cases to report the needs of the patient to

the hospital authorities with dispatch. This will permit preparing the operating room before the return of the ambulance or the sending of such other assistance as may be necessary.

SUB-COMMITTEE ON THE DEAF AND HARD OF HEARING

Contemplated Program of the Sub-Committee on the Deaf and Hard of Hearing Cooperation of all members of the Medical Profession in the State of New York is earnestly sought by this sub-committee in order to carry out the following objectives: To raise the standards of otological care of children in the schools for the deaf which will include Working for earlier admittance to the schools, a visiting otologist for each school and a program for the non-placement of children with hearing impairments in these schools for deaf children. Much has been achieved during the past three years in raising the standards of care of the deaf children, but there is much more to be desired.

The Conservative of hearing of all school children in the State by obtaining for them, proper and necessary education and otological care. Hearing impairments must be discovered early if they are to be properly treated and hearing losses arrested. Legislation recently enacted provides for the early discovery of hearing losses through scientific methods. Recent legislation also provides for reporting by parent, or guardian or physician of the young deaf or hard of

hearing child under six years of age to the State Department of Health. Proper recommendations are then made to the child's parents for medical and educational care. This will insure the early discovery of deaf or hard of hearing children and with proper placement in a deaf school or educational care in the public school, much will be accomplished.

We have yet to provide for adequate educational care in the way of lip-reading instructions for the child with varying degrees of hearing impairments in our public schools. The Committee is also endeavoring to spread information regarding educational opportunities, recent developments in scientific hearing tests, and in the early diagnosis and care of infected ears or hearing losses caused by obstructions. Each County Medical Society is earnestly asked to cooperate with the Sub-Committee in their efforts to conserve hearing in the children of the State.—New York League for Hard of Hearing, 480 Lexington Ave., New York City

LEO M. SCHIFF, M.D.

ESTELLE E. SAMUELSON, *Secretary*

PRO AND CON

The Kentucky State Department of Health has issued a ruling, prohibiting the use of graduated prescription bottles in which the graduations are blown into the glass. It has been found that not infrequently in the case of such bottles the volume of content has no relation to marking.

The Department of Forensic Medicine of New York University has been reorganized under the direction of Dr. Harrison Martland, who succeeded Dr. Charles Norris as Professor of Forensic Medicine in January 1936. In addition to undergraduate work, the department has developed graduate instruction leading to the degree of Med Sc D and short, intensive courses in specialized branches of medicolegal work. The Charles Norris Fellowship in Forensic Medicine has been established which is open to candidates applying for work toward the degree.

Six times as many patients sued their doctors in 1935 as in 1921, and recent figures indicate that in 1936 approximately one doctor in twenty will be a defendant in a malpractice trial, says Henry Morton Robinson in *The American Mercury*. At the same time, however, although the volume of

such litigation is increasing tremendously, less than one-tenth of it is successful. The patient rushes in with his grievance, sincere or otherwise, but nine times out of ten he retires with nothing tangible except the cost of a lawsuit.

One thousand Jewish doctors, representing a sixth of the total, departed from Germany during 1935, according to figures made public by the Joint Distribution Committee. The committee also reported refusal of licenses of young Jewish doctors in Germany. Also

There is no longer any chance of access for young male students to the universities, since in order to matriculate one must give proof of having done "work service," from which Jews are excluded.

Figures made public show that there is less than one in one hundred Jewish doctors under thirty-five in Berlin. Exactly 35.9 per cent of all Jewish doctors in Berlin are over fifty-five. Identical conditions prevail elsewhere in the country, with the average age of those remaining "constantly rising."

"There's that man who's always giving women something to talk about."

"A scandalmonger, eh?"

"No, a surgeon"—*Portland Press Herald*

Medical News

Secretaries of County and local Medical Societies are requested to send the programs of coming meetings to this department one month in advance, for the information of members who may be interested

Albany County

THE SEPTEMBER MEETING of the Medical Society of the County of Albany was held in the Auditorium of the Albany College of Pharmacy, September 30

The scientific program "*The Part of the General Practitioner in the Syphilis Control Program*," by Dr Earl D Osborne, Professor of Dermatology and Syphilology, University of Buffalo, Buffalo

Bronx County

DR. HENRY FRIEDLAND, Secretary, reports that the regular monthly meeting of the Bronx County Medical Society will be held at Burnside Manor, 85 West Burnside Avenue, October 21, at 8 30 P M

The program follows

Address of Retiring President, Milton Goodfriend, M.D

President's Inaugural Address, Clarence O'Connor, M.D

"Committee on Trends and Medical Practice of the N Y State Medical Society," Terry Townsend, M.D

"The Doctor and the Public," Mr Dwight Anderson.

"The New York State Journal of Medicine," Peter Irving, M.D

"The New York State Medical Society," Floyd Winslow, M.D

DR. GEORGE FRANCIS PATTON, a specialist in diseases of the eye, who won the Croix de Guerre in the World War as a lieutenant, medical corps, with the 165th Infantry, in France, died suddenly on September 14 of a heart attack at his home, 2,123 Bathgate Avenue, the Bronx. He was forty-nine years old

Dr Patton was educated at St. Ann's Academy, Fordham University and the Medical School of the University of Maryland, where he received his M D in 1910. He was on the surgical staff of the Bronx Eye and Ear Infirmary and an honorary surgeon of the New York Police Department.

Early in 1918 Dr Patton suffered from a severe gassing while at the front with his regiment and for a time was thought dead. The Germans had drenched his position with gas and, although he was safe himself, as he was wearing a mask, he found that, thus impeded, he could not efficiently aid his comrades and therefore threw aside his mask. He recovered after a long stay in a hospital

Chautauqua County

THE FALL MEETING of the Chautauqua County Medical Society was held at Newton Memorial Hospital, Cassadaga, Sept. 22

Dinner was served, followed by a business meeting and scientific session. An address, "Diseases of the Chest and Their Surgical Treatment," was given by Dr Richard Overholt of the Lahey clinic, Boston

Dutchess County

DR. WILLIAM HALLOCK PARK was the speaker at the fall meeting of the Dutchess County Health association on Sept. 24, at the Millbrook Golf and Tennis club, Poughkeepsie. The reports of the Pawling and Wappingers Falls township health committees also were read.

Erie County

FIFTY-FIVE PRACTICING physicians attended the sixteenth annual postgraduate course at the school of medicine of the University of Buffalo. Representing thirty-three universities and fourteen states, this is the largest number in attendance since the course was inaugurated in 1930

The two-weeks course, with a series of clinics, ward walks, and staff conferences, was designed for the general practitioner who wished to review recent medical developments

DR. PETER LIVINGSTON CARTER, seventy-nine, family physician who practiced in Buffalo for the last fifty years and had been connected with numerous hospitals, died in his home on Sept 13, after an illness of about a year

Dr Carter had been attached to the medical staff of the City Eye, Ear and Throat dispensary, the Lexington Heights hospital, Sisters hospital, and the associate staff of Millard Fillmore hospital. In 1921 he was consulting at Buffalo

For several years during the World war he was head physician at the Curtiss Aeroplane & Motor Co, Inc.

Franklin County

DR. G F ZIMMERMAN, of Malone, Secretary of the Medical Society of the County of Franklin, reports that the regular annual meeting will be held in Malone on Oct. 28.

Fulton County

THE FULTON COUNTY MEDICAL SOCIETY opened its Fall season with a meeting Sept 17 in the Hotel Johnstown. Members participated in informal discussions and talked over future activities. At the next meeting October 15, it is expected that Dr E K Cravener of Schenectady, orthopedic specialist, will give a paper.

Herkimer County

THE HERKIMER COUNTY Medical Association met Sept 15 at the Mayflower, Herkimer-Middletown Road, with the president, Dr Harold F Buckbee, Dolgeville, presiding.

The physicians discussed informally the subject of workmen's compensation fees. The nominating committee was instructed to prepare a slate of officers and present it to the group. Election will be at the annual meeting in December.

The association, which once met but four times yearly, will probably continue on the present schedule of six meetings a year.

Kings County

DR EDWIN R HODGE, seventy-six, major, U S Army Medical Corps, retired, died at Veterans Hospital 81, the Bronx, Sept 18.

Dr Hodge served in the Spanish-American War, the Philippine insurrection and the World War. He retired from the Army in 1933. He was a member of the United States Pharmacopeia Committee in Washington for a number of years, and lectured on anatomy at the Army War College.

Born in Plymouth, England, he came to the United States when a boy, attended Yale University and was graduated from Johns Hopkins Medical College. He lived at 485 Bay Ridge pkwy, Brooklyn.

Two sons, two brothers and two sisters survive. He was buried with military rites at Arlington National Cemetery.

THE REGULAR MONTHLY meeting of the Medical Society of the County of Kings will be held on Oct. 20 in the MacNaughton Auditorium, 1313 Bedford ave, Brooklyn.

THE COMMITTEE ON Medical Motion Pictures announces the following program to be given on Wednesday afternoons at 4 30 o'clock in the MacNaughton Auditorium.

Oct 21—"Plastic Surgery," Dr Walter A Coakley.

Oct 28—"Fractures," Dr Joseph Tenopyr.

THE FIRST MEETING of the Brooklyn Thoracic Society will be held on Oct. 16, at the County Medical Society building.

The guest speaker will be Dr Allan Krause who will address the Society on "The Modern Management of Clinical Tuberculosis."

Monroe County

MORE THAN 1,000 physicians and surgeons practising within a 150-mile radius of Rochester, have been invited to a three-day post-graduate medical conference to be held under the auspices of the University of Rochester School of Medicine and Dentistry November 5-7.

Inspection of various departments, clinical and laboratory demonstrations are scheduled for the morning sessions. The Eastman lecture, by an outstanding medical authority, will be given Friday evening, November 6. Brief presentations of practical clinical problems will be given at two afternoon meetings.

The medical men have been invited to attend the concert of the Rochester Philharmonic Orchestra, November 5, and the Rochester-Union football game, November 7.

LECTURES BY Dr George W Corner and Dr Elbert B Ruth were the high lights of the meeting of the Medical History Club in Strong Memorial Hospital amphitheater in Rochester, September 28.

Doctor Corner talked on "A Medical Mystery of the Thirteenth Century," and Doctor Ruth's subject was "Resurrection Days."

Nassau County

DR H G WAHLIG, Secretary of the Medical Society of the County of Nassau, reports that the next meeting will be held on Oct. 27 at the Nassau County Bar Association Club House at Mineola.

A NASSAU COUNTY doctor was outstanding among the Brooklyn and Long Island exhibitors at the 22d annual flower show of the American Dahlia Society held for the first time at the Horticultural Hall of Rockefeller Center in conjunction with the Dahlia Society of New Jersey. The show includes 351 classes for amateurs, professionals and members of garden clubs.

A sweepstakes winner in a class open to all exhibitors and winner of the Charles H Ruscher Memorial Cup, Dr Bruce B Preas of 387 Merrick Road, Rockville Centre, captured thirteen first prizes and two second prizes.

Dr Preas, Health Commissioner of Rockville Centre as well as Police and Fire Department surgeon, has been raising dahlias as a hobby for nine years. A bacterial blight and the recent gale curtailed his exhibit.

Known throughout Long Island as an outstanding amateur dahlia grower, Dr Preas' seedling, Betty Lindgren, won the title,

Miss Tricentenary, as the most popular flower at the Seaford flower show last week.

He is a vice president of the American Dahlia Society and a member of the Dahlia Society of New Jersey, the Ohio State, Midwest and Rockville Centre Dahlia Societies. His dahlias won awards at the recent National Dahlia Show in Detroit and at the Freeport show as well as at the Seaford exhibition. He will enter dahlias in the Camden, N. J. and Washington, D. C., shows.

DR. GEORGE N. LEONARD of Lawrence, pediatrician, attached to the staff of St. Joseph's hospital and widely known throughout The Branch, was honored by his colleagues with a farewell dinner given at Cedarwood Country Club, Woodmere. He will leave to take up practice at Miami Beach, Fla. at an early date.

Dr. Ferdinand Herman, president of the Rockaway Medical society, expressed regrets of the membership of that organization at Dr. Leonard's leaving. Others who spoke briefly were Dr. Martin L. Sowers and Dr. Leonard S. Rau of Woodmere, and Dr. Irving Gray of Brooklyn. A leather medical case was presented Dr. Leonard as a farewell gift.

Dr. Leonard came to The Branch from Albany twelve years ago and established a home and office at 1 Central avenue, Lawrence. He began specializing in pediatrics and in a few years earned a wide reputation in The Branch and Rockaways.

New York County

WHAT THE CITY HAS DONE for the sick unemployed since the start of the medical and nursing service of the Emergency Relief Bureau in December 1932 is told in a report by Charles F. McCarthy, director of the service.

More than 426,750 relief cases received medical and nursing treatment during the period in question, the number under care during the first half of 1936 being 760 per cent greater than the number cared for during the first six months of the service. This, Dr. McCarthy said, indicates how necessary it was to expand the service to meet the health needs of the unemployed. He emphasized, however, that the cost of caring for an individual case during the first half of 1936 showed a reduction of forty-seven per cent as compared with the 1933 cost.

The report stressed that half of the cases would have required hospitalization if the services of the medical unit had not been available.

"Hospitalization would have cost three times more than the bureau's cost per case," Dr. McCarthy said. "Consequently, while

the bureau has spent \$3,002,194.07 in caring for 426,750 cases during the past three and a half years, this expenditure actually represents a saving of \$1,500,000 in regular budgetary expenditures."

The work of the medical and nursing service is done with the assistance of a panel of 4,000 physicians and a panel of 1,800 pharmacists under contract with the ERB. Physicians receive a standard fee of \$2 for a relief visit and serve in rotation. When a doctor is authorized to visit a relief patient he is given the name of a pharmacy to which he may send the prescription. Nurses are recruited from existing visiting nurse organizations.

DR. WALDO H. SANFORD, sixty-four, of 617 W. 168th St., well known throughout the Washington Heights area and a lieutenant colonel in the Medical Corps during the World War, died in Harkness Pavilion, Columbia Medical Center on Sept. 15.

He was driving his automobile through Audubon Ave. when he became ill. He stopped his car and a patrolman drove him to the hospital.

He was vice president of the James H. Torrens Democratic Club of the Twenty-fourth A. D., a member of the New York County Medical Society and of the Richard J. McNally Post of the American Legion.

He was also affiliated with the Fred A. Meyer Post of the Veterans of Foreign Wars and with the Audubon Medical Society. He served eighteen months in France during the World War.

STATE INDUSTRIAL COMMISSIONER Elmer F. Andrews has announced the appointments of Dr. Edgar Mayer of Saranac Lake and New York City, and Dr. J. Burns Amberson, Jr., of New York City, nationally recognized authorities on tuberculosis and silicosis, as "expert consultants on dust diseases" to the State Department of Labor.

Dr. Mayer also was recently appointed medical director of the project for the study of silicosis at the Cornell Medical College and the New York Hospital, sponsored by the New York City Department of Health and the New York Tuberculosis Association. Dr. Mayer is consultant attending physician at the New York and Bellevue hospitals, consultant physician to Otisville and Loomis Sanatoria, to the Broad Street hospital, New York City and to the Preventorium of Tuberculosis, Farmingdale, N. J., and consultant on radiation of the Council of Physical Therapy of the Medical Association. He is also assistant professor of clinical medicine at Cornell Medical College.

Dr. Amberson is professor of clinical medicine, College of Physicians and Surgeons, Columbia University, assistant professor of

clinical medicine New York University College of Medicine, visiting physician, tuberculosis service, Bellevue Hospital, consulting physician, Loomis Sanatorium, attending physician, New York State Tuberculosis Hospitals, member of Medical Research Committee, National Tuberculosis Association and New York Tuberculosis Association, president of the Association of Tuberculosis Clinics

Onondaga County

THE OPENING EVENT of the season for the Syracuse Academy of Medicine was its annual joint meeting with the Utica Academy of Medicine at the Syracuse Yacht and Country Club on Sept. 17.

The program included golf in the afternoon, a clambake at 6 o'clock, and a scientific session during the evening. Speakers at the latter meeting, arranged by the Utica representatives were Dr. J. R. Grant, who discussed "Venoclysis—Uses and Abuses," and Dr. T. Woods Clarke, whose subject was "Little Recognized Types of Allergy."

Oswego County

LAWs RELATING to medical care of welfare cases were outlined and explained by Commissioner of Welfare Lee C. Loomis of Mexico in a talk at a dinner meeting of the Oswego County Medical Society in Oswego, at the Elks' club, Sept. 17. Physicians from all parts of the county were present. The Society will hold its next meeting in November, time and place to be announced.

Otsego County

THE MEMBERS OF THE STAFF of the Homer Folks Tuberculosis hospital presented a scientific program Sept. 16 at a meeting of the Otsego County Medical Association held at the hospital. There were twenty-five present. The society was entertained at dinner in the hospital.

Dr. E. H. Kerper discussed sanitarium treatment of tuberculosis and demonstrated with x-ray films and presented patients. Dr. A. M. Stokes spoke on pneumothorax and pneumonolysis, also using x-ray pictures and patients in the demonstrations. Surgical treatment of the disease was discussed by Dr. E. F. Butler, who explained phrenicectomy, thoracoplasty and various other operations used in the treatment. He used x-ray and patients for his demonstrations. Dr. Ralph Horton, superintendent of the hospital, spoke on differential diagnosis of tuberculosis, demonstrating with x-ray films.

Queens County

THE PROGRAM of the Medical Society of the County of Queens at its meeting on

Tuesday evening, Oct. 27, will be a symposium on obstetrics, as follows:

"Obstetric Education as an Approach to Lower Maternal and Infant Mortality Rates," Edward S. Godfrey, Jr., M.D., Commissioner of Health of the State of New York.

"Prenatal Care," Harriet White, M.D.

"Analgesia and Anesthesia in Obstetrics," Moses Cohen, M.D.

"Conduct of Normal Labor," Henry Eichacker, M.D.

"Vomiting in Pregnancy," Walter Kerby, M.D.

"Bleedings in Early and Late Pregnancy," George J. Lawrence, M.D.

"Toxemias of Pregnancy," James P. McManus, M.D.

The papers to be presented by the members of the Maternal Welfare Committee will be limited to ten minutes each.

Graphically Illustrated Moving Picture, "Mechanism of Normal Labor" (Fifteen minutes).

Discussion.

THE BOARD OF CENSORS of the county society has issued warning against "the practice of certain members to give to the public press accounts of rare operations performed by them, the installation of new equipment in their offices or the contemplated construction of new hospitals in which they are interested."

The censors also say "Ads in church journals, private telephone directories and also the placing of signs in office windows denoting specialties are also in violation of the Code of Ethics of our Society. It may seem old fashioned and antiquated because of the changing economic conditions but, until there is further change in our Code of Ethics, we must all abide by it."

THE AUXILIARY of the Medical Society of Queens County held a bridge-luncheon at the Amber Lantern Inn, Flushing, the afternoon of Oct. 14. Plans are under way for an Armistice Eve dinner-dance.

DR. DAVID B. KIRCHENBAUM, Long Island City, who has practiced general medicine in Woodside and vicinity for almost ten years, was graduated with the degree of Bachelor of Laws from the Brooklyn Law School of St. Lawrence University on Sept. 10.

Dr. Kirchenbaum intends to continue the practice of medicine and says that he studied law as a hobby.

His law studies, started two years and three months ago, grew so interesting that he continued them in his spare time, taking Summer courses, until he won his Bachelor of Laws degree.

Few men achieve degrees in both law and medicine. Among the prominent names of those who are both doctors and lawyers are Supreme Court Justice Phillip J. Brennan and Dr. George I. Swetlow, professor of

medicolegal jurisprudence at the Brooklyn Law School

AT THE COMMENCEMENT of the John B Stetson University on June 8, the honorary degree of LL D, was conferred on Dr John Joseph Kindred, Chief Consulting Physician to the River Crest Mental Hospital at Astoria

Dr Kindred has been for several years professor of Medical Jurisprudence in the Law Department of this University and also has an LL B, as well as an MD degree. He was for ten years a member of the U S House of Representatives from Queensboro New York City, retiring voluntarily six years ago

Dr Kindred is the retiring president of the National Association of Private Psychiatric Hospitals

Tompkins County

THE BIGGS MEMORIAL HOSPITAL will give Tompkins and eight neighboring rural counties "facilities for the prevention and treatment of tuberculosis fully equal to those of any urban area"

This statement was made by Dr John K Deegan, physician in charge of the new state sanatorium overlooking Cayuga Lake, in an address to the Kiwanis Club at the Ithaca Hotel, Sept. 21

Doctor Deegan disclosed that the charge for treatment will be \$250 per day per patient, which will be far short of the actual cost. This charge will include all services, with no extra fees

A patient or his relatives will be required to pay if investigation shows they are able, otherwise a monthly bill will be sent to the Board of Supervisors of the county where the patient resides

The main hospital, Doctor Deegan stated has a rated capacity of 200 patients, who will be drawn from the counties of Tompkins, Cayuga, Chemung, Cortland, Schuyler, Seneca, Tioga, Wayne, and Yates. In addition, the institution includes a children's building to care for fifty children

Two important branches of the hospital's service, said Doctor Deegan, will be a traveling clinic and public health nursing. The object is to discover every case of tuber-

culosis at the earliest possible stage and place it under treatment.

Among services of the institution will be a clinical and pathological laboratory, a surgical suite, rooms for eye, ear, nose and throat, a dental office and laboratory, an outpatient clinical department, X-ray facilities, and rooms for occupational therapy and adult education

A skeleton staff has already assumed its duties

The hospital will be in stages of organization for the next 15 months or so, Doctor Deegan said and no formal dedication will be held before 1937. The children's unit will be the last to be opened

Visitors are welcome to inspect the new hospital at any time during the period of organization, and will be personally escorted by some member of the staff

Washington County

THE ANNUAL MEETING of the Medical Society of the County of Washington was held Oct. 6 at the Court House at Hudson Falls. The program included "Presenting a Case of Displacement of Heart," Dr R C Paris, "Paper on Empyema," K. Creevy, President's Address "Treatment of Peritonitis associated with appendicitis" G M Casey

Dr Maslon was present to represent the Economic committee of the Medical Society of the State of New York. Dr W C Thompson, Medical Consultant Division of Social Hygiene, spoke on Treatment of Syphilis

Westchester County

BRONCHOSCOPIC aid in the diagnosis and treatment of post-operative pulmonary complications was the subject of the address delivered Sept. 15 before the Westchester County Medical Society at its first fall meeting held in Grasslands Hospital. The speaker was Dr Gabriel Tucker of Philadelphia, professor of clinical bronchoscopy at the University of Pennsylvania School of Medicine

The Society meets again Oct. 20 at Grasslands, when the subject will be maternal welfare, with particular reference to operative obstetrics in hospitals and better prenatal care for expectant mothers

HOW A NOISE ANNOYS

Experiments at Bellevue Hospital are reported by Dr Foster Kennedy of Cornell who demonstrated that the noise resulting from the explosion of a paper bag raised the brain pressure to four times normal for seven seconds, and that thirty seconds elapsed before the pressure returned completely to normal. Trephined patients were

used for these experiments, the pressure being measured directly from the brain surface. "The undoubted effect of constant noise," according to Dr Kennedy, "is disturbance of the blood vessel apparatus, and the increase in the degenerative processes in the heart and arteries"

Counsel Medical Society of the State of New York

Insurance—Overdose of Drug as Accidental Cause of Death

A recent ruling made by the Appellate Division of the Supreme Court of this State dealing with a suit to recover an accidental death benefit under a policy of life insurance should be of interest to the members of the medical profession.*

The plaintiff in the case was the beneficiary named by her husband in his life insurance policy. For approximately two years prior to his death, the assured had been suffering from diabetes. In December 1933, he had consulted his physician concerning complaints of being restless and unable to sleep. The doctor had given him a prescription of veronal in one and one-half grain tablets to be taken twice daily. On December 31, the husband had arisen at about eleven in the morning complaining to his wife that he was suffering from a severe earache, and the wife suggested that he take some aspirin. A search was made by them to find aspirin about their apartment, and an attempt was made to borrow some from a neighbor but unsuccessfully. The wife thereupon suggested that her husband might take some of the veronal tablets.

About an hour and a half later the man stated that he had taken the veronal and it had made him feel sick. His wife responding to his complaints found that he was in an apparent state of coma, and called the family physician. Emergency treatment was rendered, and the man was taken to a hospital, but he failed to regain consciousness, and died three days later.

The cause of the man's death according to the testimony upon the subsequent trial was unquestionably veronal poisoning, but there was not even a suggestion that death was caused by an attempt at suicide.

The widow instituted an action against the insurance company to recover accidental death benefits upon her husband's policy, the pertinent provision of which entitled the beneficiary to certain monies upon proof of death occasioned as a result "of bodily injuries effected solely through external violent and accidental means." There seems to have been no question that the veronal was taken intentionally, and not accidentally, and upon the theory that the facts did not justify bringing the case within the terms

of its policy the insurance company defended the case.

The trial of the case resulted in a judgment in favor of the plaintiff, and an appeal to the Appellate Term of the Supreme Court, resulted in a reversal with a dismissal of the complaint in favor of the defendant company. However the action was further appealed to the Appellate Division which reinstated the judgment of the trial Court. In arriving at that determination various precedents were reviewed by the Court which are of interest.

Various cases which had been considered as authorities for the defendant's contention showed that in certain instances of unanticipated death brought about by intended means the Courts had ruled that death had not resulted from "accidental means."

In one such case, death had been caused by appendicitis. The proof had shown that the deceased had been riding a bicycle and had in doing so caused certain muscles to be used which had irritated an abnormal appendix, and the tissues surrounding it. The appendix had ruptured by reason of its weakened condition. In that case the Courts had ruled in favor of the insurance company.

Another case in which the ruling was likewise against the plaintiff was one in which the deceased had gone to a dentist for the extraction of a tooth. At his request the dentist administered a small quantity of nitrous oxide gas and the patient died. An autopsy showed the death was caused by status lymphaticus. The decision was that the death was not covered by an accidental death policy.

In still another instance where the same conclusion had been reached, the deceased had on the day of his death been taking a course of physical culture in a gymnasium. Massage of the abdomen in the gymnasium had brought about an intra-abdominal hemorrhage. The immediate cause of death was given as "Intra-abdominal hemorrhage" resulting from "Probably cancer of the intestines," but the contributory cause was stated as "Hemorrhage was caused by either some electrical or manual massage on abdomen received in a gymnasium."

However in another case, where the opposite conclusion was reached, the assured had died from sunstroke. He had intentionally exposed himself to the sun in the

* *Mansbadier v Prudential N. Y. Law Journal*, Sept 25, 1936

conduct of his business for an unusual number of hours thereby bringing on a fatal sunstroke, and the Court had held the death caused "through accidental means"

Another case under consideration was one where the claim of causation had started with a pimple on the lip. It became large and inflamed, and a physician attending the assured opened the lip and attempted to administer remedies. Within a week the man became paralyzed and blind, and died the next day. His cause of death was given as inflammation of the brain produced by staphylococcus aureus. The proof indicated that undoubtedly the germ came from the infected pimple and that a puncture by instrumentation had caused an infection of the deeper tissues leading to death. The Court of Appeals ruled that upon such proof the death was produced by accidental means.

The Appellate Division determined that the venereal poisoning case fell within the category of the last two mentioned cases, and on that authority ruled that although an unusual and unexpected result had followed an intended act, death was caused by accidental means so as to entitle the widow to recover against the insurance company.

Treatment of Pruritus Ani

A man fifty-four years of age consulted a general practitioner with complaints of rectal pain and itching. He told the doctor of having had rectal disturbances for a long time and of having undergone various forms of treatment. The doctor on examination found a fissure and a few hemorrhoids and diagnosed the condition as pruritus ani. He advised alcohol injections for the treatment of the condition, and the next day administered to the patient a local anesthetic of novocaine and injected a thirty per cent solution of alcohol into the perianal region. The injections were made into the subcutaneous tissue about one-quarter of an inch deep, four injections being made in all and a total of approximately thirty c.c. of the solution being administered. The doctor treated the hemorrhoids and fissure by electrocoagulation, dry dressings were applied. The patient was allowed to go home the same day after the operation and after-care was undertaken by a physician who resided in the neighborhood of the patient.

About a week after the treatment a pararectal abscess developed which was treated under the direction of the first doctor by the local physician. A few days later, although the patient's condition was satisfactory, he discharged the two doctors that were caring for him and went to another physician.

The next the doctor who had performed the operation heard of the patient was the service of a summons upon him for the purpose of bringing a malpractice action against him. The plaintiff made the claim that the technic of the operation was improper and that the after-care was also improper. Upon the trial of the action, the plaintiff called as a witness the last physician who had treated him. He undertook to testify that the defendant had departed from proper and approved practice in his method of carrying out the Buie technic of alcohol injections. Practically all of his testimony, however, was eliminated upon cross-examination and at the close of the plaintiff's case the Court on motion of the attorney for the doctor dismissed the complaint. The plaintiff took an appeal from the judgment in favor of the doctor but never actually brought the appeal on for argument.

Treatment of Infected Index Finger

A middle-aged woman consulted a physician with respect to an infected index finger and told him that sometime before she had pricked her finger with a safety pin and that it had become very sore. The doctor incised the end of the finger making an incision about one-quarter of an inch long and one-sixteenth of an inch deep liberating a few drops of pus. He applied a dressing and gave the patient a prescription for a solution of Aluminum Acetate and instructed her to soak the finger in that solution. The next night a telephone call was received at the doctor's office from the patient at a time when the doctor was out of the office caring for another case. When he returned, he undertook to call upon the patient but learned that she had gone under the care of another doctor. He never saw her after that time.

It appeared that the infection had become a great deal worse and the patient had entered a hospital where she remained under care for two weeks. During that time various incisions were made in her hand and wrist to establish drainage. The end result caused by the infection and the treatment necessitated by it was that the patient's thumb and finger became badly crippled and ankylosed.

A malpractice action was instituted against the doctor in which the charge was made that the defendant improperly treated the condition and that due to his negligence the patient had suffered the bad result. When the case was reached for trial, the plaintiff was not ready to proceed and sometime later the action was dismissed by reason of the plaintiff's failure to prosecute the same.

Treatment of Dislocated Shoulder

In response to a telephone call a doctor engaged in general practice called at the home of a middle-aged woman who had just been injured by being struck by an automobile. She complained of pain in her right shoulder and the doctor upon examination diagnosed her condition as a dislocation upward of the right humerus and of the outer end of the right clavicle. Without an anesthetic he reduced first the dislocation of the humerus and then the dislocation of the clavicle. He applied adhesive strips and sent the patient to a hospital for further examination. X-rays confirmed the diagnosis and that the dislocations had been reduced and the doctor continued with the care of the case. The patient's condition progressively improved but when he undertook to manipulate the arm she complained of pain and tenderness and would not cooperate to a satisfactory extent.

At the end of six weeks the patient was in such condition that the shoulder straps were removed and at the end of eight weeks she was discharged as practically cured, although she still complained of tenderness when moving her arm.

A malpractice action was instituted on behalf of the patient in which the claim was made that the doctor was negligent in treating the case, that he had prolonged the period of disability and had caused her to have a permanently painful and disabled shoulder and arm.

The case was put on the calendar but the plaintiff's attorney was never ready to try the case and finally after some time had elapsed a motion was made on behalf of the defendant to dismiss the case for lack of prosecution. At that time the plaintiff's attorney stipulated to discontinue the action.

Treatment of Acne

A young woman consulted a physician in general practice complaining of pimples on her face. The doctor found a condition of acne vulgaris and suggested ultraviolet ray treatment and injections. This form of treatment was administered to her over a period of about three months. When the doctor last treated the patient the eruptions were largely cleared up and the result in general was satisfactory.

The doctor brought an action to recover his fee for professional services and the patient responded by bringing an action in a Court of a higher jurisdiction charging the doctor with malpractice in the treatment of the case. The claim was that his treatment had caused scars on the face of the patient.

Before the malpractice action could be reached for trial the doctor's action for his fee for professional services was reached and a settlement was entered into whereby the doctor received a substantial portion of his fee. No reservation was made in connection with the settlement reserving the patient's right to maintain a malpractice action against the doctor. Subsequently the answer interposed on behalf of the doctor was amended setting forth the facts of the disposition of the doctor's action for his fee as a defense. Upon the answer being so amended the plaintiff's attorney consented to discontinue the action.

Alleged Burn Following X-ray Treatment

A woman thirty-six years of age consulted a physician specializing in dermatology with respect to a complaint of prickly heat rash. Examination showed that she had a dry, scaly reddened rash all over her back and sides. He prescribed a salve for the condition and on that occasion administered to her a quarter of a skin unit of x-ray upon several areas over her back and sides. She returned to the doctor about three weeks later and her condition was improved satisfactorily and again similar x-ray treatments were administered.

Thereafter the patient made the claim that she had sustained an x-ray burn and brought a malpractice action against the defendant on the basis. A physical examination was made on behalf of the defendant prior to the trial and it was ascertained that there was present a trivial change in the color of the pigmentation of the skin where the x-ray had been administered. The case came on for trial as a non-jury case and plaintiff called a witness who testified that the patient had sustained an x-ray burn which had been produced by the first treatment and aggravated by the second treatment. The defendant denied that the patient had ever been burned and testified that her only reaction to the first x-ray treatment was a slight tanning, which would naturally be expected as a result. He testified that the patient had never received any x-ray burn and that the amount of x-ray dosage administered to her was too weak to cause any actual burn. The doctor who made the physical examination on behalf of the defendant corroborated him in his opinion that the treatment was proper and that there had been no x-ray burn.

At the conclusion of all the testimony the Court directed judgment in favor of the defendant, thereby exonerating him of the charges of the malpractice action which had been brought against him.

Across the Desk

Old and New Styles in Automobile Injuries

"AUTOMOBILE INJURIES CHANGE with the changes in car models," remarked a leading surgeon of New London, a few days ago, who has handled a large number of motor-crash victims "Take the 'turret top' of metal on the new cars," he went on "Since that came in, we have had many more injuries of the neck and the lower part of the spine The roof of the new cars is not only made of metal, but it is lower, and the floor is higher, so that the passenger is thrown violently against an impenetrable surface, and his neck or back is injured The older models had roofs made of fabric, with more room, and we didn't have so many injuries of that sort. A little while ago a man was brought into the hospital who was riding in a car like yours"—revealing the sad fact that this scribe drives an old model—"and when he was thrown against the roof, his head went right through, not very comfortable, but it saved him serious injury "

So it looks rather as if we can date the motorist's car by the character of his injuries as he comes in on the stretcher We can imagine the spiffy nurses turning up their pretty noses "He has scratches on his ears where his head went through the roof His car must be out of date " In the next room is a motorist whose spine has been twisted into the shape of the letter S Clearly the owner of an up-to-the-minute model, a patient of distinction. "Was your husband's back injured?" inquires Mrs Witherspoon with a catty smile. "Not at all," replies Mrs Fogg, and her social status slips a couple of notches immediately

Slashed by Jewelry

"Some of the motor-manufacturers are ornamenting the gadgets on the instrument-board with diamonds and emeralds and other cut stones," continued the surgeon "When the car hits a tree or a telephone pole, the passenger sitting next to the driver is hurled down into this display of jewelry, and his—or more often her—face is badly cut up It would save a great deal of painful and disfiguring injury if the manufacturers would avoid having so many projecting knobs and handles on the instrument boards A smoother board, with the present shatter-

proof glass in the wind-shield, would save many of the most distressing injuries we now have to deal with "

A couple of years ago two makes of cars came out with front bumpers presenting sharp edges pointing forward, something like the deadly scythes that projected from the war-chariots of the Assyrians The knees of pedestrians unfortunate enough to get in the way were badly smashed up, and the knife-like bumpers were changed, but many cars carrying them are still on the roads

The craze for a "change" and for something "new" does not always bring something better, and where the innovation turns out to be actually injurious, a change back again is a sign of sound judgment. "I understand," said the New London surgeon, "that the 1937 models will have more room between the floor and the roof, and I hope that will lessen the number of neck and back injuries " Certainly if the passenger is still to be catapulted about, he should at least be given room for his gyrations

Places of Safety and Peril

'What is the safest place in the automobile?" the surgeon was asked

"The safest place is behind the driver's wheel," he replied If he is correct, then, it may frequently happen that the one who is responsible for the crash may, sardonically enough, suffer the least

"And what is the most dangerous position?"

"The middle of the back seat," he answered. "It is the most dangerous because the passenger has nothing to seize hold of to save himself The two people on the ends of the rear seat can grasp handles or strips or the door-frame or something to break their fall, but the person in the middle is shot directly through space onto the edge of the front seat. A common result is a dislocated hip "

Here the surgeon assumed the exact sitting posture of the passenger, with knees and hips bent in a 90° angle

"The knees strike the back of the front seat, while the hips strike the edge. A patient was brought in the other day with both hips dislocated and both legs broken just below

SCIENTISTS EXAMINE FIRST TRANSPARENT WOMAN

Left to right Dr Dean De Witt Lewis, Surgeon in Chief of Johns Hopkins Hospital, Baltimore, Md., who unveiled The Camp Transparent Woman before a distinguished gathering of prominent medical authorities, noted scientists and leading public health officials, Dr Roy Chapman Andrews, Director, American Museum of Natural History, New York, who also spoke at the ceremonies which were nationally broadcast, and S H Camp, President, S H. Camp & Company, Jackson, Mich., who brought the Transparent Woman to the United States as his contribution to public health education.

the knee. He had been in the middle of the back seat."

Who can say, after this, that the much-abused "back-seat driver" hasn't good reason for calling out her words of caution now and then? She is in the place of danger

A Handle that Makes Mischievous

Our surgical friend also mentioned another feature of the motor-car that has its dangers. It is the door-handle, shaped much like a hook, located conveniently to impale anyone unlucky enough to be hurled against it in a smashup. This projecting, and sometimes pointed, piece of metal was condemned by a Detroit surgeon in a paper on automobile injuries reviewed in this department some time ago, so it clearly has come widely into unfavorable attention, but the manufacturers appear to be doing nothing to improve it. The New London doctor recalled the recent case of a pedestrian who raised his arm to protect himself as a car swooped upon him, and the door-handle caught and shattered his elbow.

It would seem merely plain common sense for the manufacturers to build their cars in a way to preserve the life and limb of the motorists, who buy their product and support their entire industry. Criticism of dangerous features by the medical men, called upon to repair the human wreckage, is really constructive, and is a service both to the public and to the industry. The manufacturer should be grateful for it. Automobile safety is bound to come, and intelligent and informed criticism will help bring it about. It cannot be doubted that far-sighted manufacturers welcome constructive criticism, and are doing all they can to make their cars safe to ride in. One such improvement, mentioned by this surgeon, is the present steel body frame, instead of the old wooden frame, apt to splinter and impale the riders in a crash. Emphasis on high speed is being eliminated from the advertising, and if the industry, the authorities, and the saner section of the public work vigorously together, the slight trend noticeable this year toward safer driving may get somewhere.

The Only Transparent Woman

IT WAS HARDLY NECESSARY for the sponsors of the "Camp Transparent Woman" to claim that she "is the first and only one in the world." Mere men who have vainly thought they could see through one or any of the daughters of Eve have learned their mistake sooner or later. In fact, this one had to be built specially for the purpose. The rest are still inscrutable. A transparent woman is so rare that this one, after being exhibited at the New York Museum of Science and Industry, is to go on a tour of one hundred cities which will last over two years. Even then the really important things about the fair sex, their whims, wishes, intentions, and dispositions, in general and in particular, will be just as much of a closed book as before.

This transparent lady, it seems, is not made of glass, as might be supposed, but of "cellhorn," a substance developed by a secret process. She was made by technical and medical experts at the famous Museum of Hygiene at Dresden, Germany, and took two years to construct, after many years of research and experiment. The exhibit was brought to America by Mr. S. H. Camp, widely known maker of physiological sup-

ports, of Jackson, Mich., as his contribution to public health education. He will donate the figure to some prominent medical school or museum for permanent exhibition after the tour.

Every bone, every organ, even the delicate veins and circulatory system are clearly visible to the observer. Electric lights around and within the figure light up all or any part of it at will.

The Transparent Woman will recall the Transparent Man, also brought from the Dresden Museum by Drs. Carl and Robert Mayo of the Mayo Clinic, where it is now on permanent display. Only three other Transparent Men have been constructed. One is in the Hall of Man at the Buffalo Museum of Science, another in the Swedish Red Cross Museum in Stockholm, and the third in the Dresden Museum.

The educational results of the tour of this exhibit to one hundred cities in two years should be incalculable. It should impel the minds of thousands to a more scientific appraisal of their own bodies, and impress upon them the importance of turning for counsel to men with scientific knowledge, training, and skill.

Books

Books for review should be sent directly to the Book-Review Department at 1313 Bedford Avenue, Brooklyn, N Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

ORDERING BOOKS

As a service exclusive to our readers, books published in this country may be ordered through the Business and Editorial Offices of the Journal (33 W 42nd St., N Y C) postage prepaid. Order must be accompanied by remittance covering published price.

Williams Obstetrics A Textbook for the Use of Students and Practitioners By Henricus J Stander, M D Seventh edition Octavo of 1269 pages, illustrated New York, D Appleton-Century Company, 1936 Cloth, \$10 00

REVIEWS

The Art of Ministering to the Sick. By Richard C Cabot, M D & Russell L Dicks, B D Octavo of 384 pages New York, The Macmillan Company 1936 Cloth, \$3 00

Dr Cabot's last, and not least important, contribution to the art of caring for the sick is a book written with the Rev Mr R L Dicks, for the use of clergymen in preparing them for their pastoral responsibilities in this matter. The problem is approached in such a tolerant spirit that the rabbi, the priest, the agnostic, will find himself heartily assenting to most of the statements. It is approached in such a wise and understanding spirit that these same readers will say to themselves "This is not only true. This is important." The psychology of the patient, his tendencies and

needs are set forth in a way that indicates wide experience from the standpoint of a physician, of a minister, and of a patient. Every doctor could profit immediately in the care of his own patients by this review of much that he knows, and some things that he has not noticed or thought about. The minister is addressed directly on why and how he can help out in the care of the sick. His first function is that of an understanding friend, there to do what he can to help. This sooner or later involves a recognition and encouragement of the usual effect of an illness toward a growth in character. Here definitions are clear, technique fully described. Listening rather than arguing, encouraging the patient to do his own thinking, but not neglecting helpful authorities

on occasion, in fact, the best principles of good teaching are presented. The aim in actual accomplishment for the patient is toward a spirit that can face failure without self pity, success without complacency, whose satisfaction so far as self is concerned is growth. This is a doctor's inadequate and necessarily brief review. No doubt a clergyman would stress other aspects of the book. Both would agree that it is wise and kind and needed.

TASKER HOWARD

The Patient and the Weather By William F Petersen, M.D. Volume 1, part 1. Quarto of 127 pages, illustrated. Ann Arbor, Edwards Brothers, Inc. 1935. Cloth, \$3.75.

This is the introduction to three volumes, planned by the author, as a series of monographs that deal with meteorological influences on normal persons and on the patient. As such, it presents a rapid survey of the field. It is a book of figures and maps—"maps dealing with the human beings that populate the land, maps that show why they are what they are and why they are becoming more so—"

This part of the work is limited to a visual demonstration of the facts available to the author. In Volumes II and III Petersen presents and develops more fully his theories of the influence of the weather and the season on such disease processes as multiple sclerosis, tabes, anterior poliomyelitis, the psychoses, etc. The subject is approached from a philosophical point of view. The author quarrels with the academic teaching in our medical schools because students are taught to think in terms of ultimate results. As Petersen puts it, "We think too pathologically." He feels that while morbid anatomy has great didactic value, after all, pathology is an end result of the disease, whereas physicians must seek the beginning of the process. He bemoans the fact that modern medicine has forgotten or neglected the teachings of Hippocrates, especially in regard to the influence of the environment on the individual. Hippocrates insisted that a knowledge of meteorology is essential for the understanding of medicine. The author stresses this thesis, and the monographs are the outgrowth of the postulates that the environment affects the patient. This applies chiefly to the immediate environment, namely, the weather and the season. He has made use of the meteorological changes to support his contention because this environmental factor can be measured with considerable accuracy. In this volume a few salient facts are pointed out but more details follow in the other volumes.

JOSEPH L. ABRAMSON

Immunology By Noble P. Sherwood, M.D. Octavo of 608 pages, illustrated. St. Louis, The C. V. Mosby Company, 1935. Cloth, \$6.00.

This book was prepared primarily for the medical student and for those seeking an introduction to the broad field dealing with infection and resistance. It covers not only the theoretical aspects of the subject, but also presents most of the common immunologic laboratory procedures which prepare the student for the practical problems he will encounter in practice.

The material is divided into relatively short paragraphs, each of which has its own title. The style of presentation is simple and almost elementary.

The first few chapters deal with infection and infectious agents host-parasite relationships, and anatomical and physiological factors in immunity. Then follow discussions on the various theories of immunity. The different types of anti-bodies and their importance in diagnosis are reviewed. Practical and theoretical considerations of toxins, anti-toxins and serums are taken up. Other subjects treated in detail include antigens, specificity, colloids, complement fixation, and hypersensitiveness. Lists of references follow each chapter. Many tables, figures and plates aid in the presentation of material.

In this book the author has achieved his purpose of effectively presenting a difficult subject in a manner which will appeal to the novice in the field.

MATTHEW WALZER

Fundamentals of Biochemistry in Relation to Human Physiology By T. R. Parsons, M.Sc. Fifth edition. Duodecimo of 453 pages, illustrated. Baltimore, William Wood & Company, 1935. Cloth, \$3.00.

Since 1923 this book has gone through five editions, the third required a reprinting. This, recommendation enough for any book, is particularly complimentary to a work that does not profess to cater to the daily bedside needs of the average general practitioner.

This book is written in an easy readable manner and presents the subject clearly, concisely and interestingly. Accuracy and thoroughness are not sacrificed to brevity. The frequent editions keep the work up-to-date.

In this edition the complicated chemistry of muscle metabolism has been given a whole chapter. Special attention has also been devoted to the fascinating subject of sterols and the sex hormones.

Altogether it is a little book that deserves a place of honor in every physician's library.

BENJAMIN DAVIDSON

Synopsis of Clinical Laboratory Methods
By W E Bray, M D Duodecimo of 324
pages, illustrated St. Louis, The C V
Mosby Company 1936 Cloth, \$3 75

The object of bringing together scattered and inaccessible recent information and the most frequently used methods of laboratory diagnosis in one manual has been well met by this practical synopsis. Not too elementary, it is definite and complete for assistance to the clinician as well as the laboratory worker, experienced or inexperienced. The selection of material, color plates, and illustrations is remarkable for such a small manual. Noteworthy are the practical adaptations and the amount of recent authentic material included. The references in the body of the text would be more outstanding as footnotes, however.

IRVING M DERBY

Manson's Tropical Diseases A Manual of the Diseases of Warm Climates Edited by Philip H Manson-Bahr, M D Tenth edition, revised Octavo of 1003 pages, illustrated Baltimore, William Wood & Company 1936 Cloth, \$11 00

Consistent with the original intention of Sir Patrick Manson, the latest edition is called a manual of the diseases of warm climates. Practically it has become a reference text book and has fulfilled a role similar to Osler's "Principles and Practice of Medicine." Because of his original researches and the contributions of the successive editions of his book, Dr Manson probably deserves his unofficial title of "Father of Tropical Medicine." Every worker in areas where tropical diseases abound has made frequent use of the material found in the chapters on diagnosis and treatment.

The present edition contains a great deal about the recent advances in the field of virus diseases. The newer methods of prophylaxis of yellow fever make fascinating reading. Since all are aware of the existence of amoebic and bacillary dysentery, endemic typhus, spotted fever, and undulant fever in eastern United States the excellent sections on these diseases are of more than academic interest. It is frequently forgotten that filariasis, schistosomiasis and other rare parasites are imported from the West Indies and other infested areas. Valuable material on all of these subjects is contained in Manson's book.

Mention should be made of the numerous beautiful plates of the malarial and other parasites, oriental skin diseases, the colon and rectum in dysentery, the sprue tongue and the particularly fine ones of mosquitoes and other insect carriers of disease.

It is fortunate that the present editor Dr Philip Manson-Bahr, has been able to carry

on in the Manson tradition and bring us a tenth edition containing all the recent advances in the field.

J A CURRAN

Pediatric Treatment. A Manual of the Treatment of the Diseases of Infants and Children designed as a reference work especially for the General Practitioner and Physicians entering the field of Pediatrics By Philip S Potter, M D Octavo of 578 pages New York, The Macmillan Company 1935 Cloth, \$5 00

This book covers, in more or less detail, methods of handling and treating disease of the infant and child. Most modern textbooks fail to cover this ground acceptably. Those physicians, far removed from the aid of good nursing care and who are unaccustomed to the detailed care of young infants will find the methods described of aid. Also the procedure for giving drugs to infants as well as many other "finesses" jotted down here and there make this volume a well worth while addition to one's library.

THURMAN B GIVAN

A Guide to Psychiatric Nursing By F A Carmichael, M D & John Chapman, M D Second edition Octavo of 175 pages, illustrated. Philadelphia, Lea & Febiger 1936 Cloth, \$2 25

This is a volume of pocket size that tells briefly the story of mental disease from the very early conceptions to the present status of psychiatry. As the title implies, it is primarily for nurses and for them defines certain psychiatric phrases and terms, and follows through with a descriptive classification of the psychogenic and organic reactions and their etiology. The chapters on treatment and the ethics and duties of psychiatric nursing should be particularly helpful to the serious reader.

A E SOPER

Sex Behavior in Marriage By Charles A. Clinton, M D Duodecimo of 159 pages New York, Pioneer Publications, Inc, 1935 Cloth, \$2 00

This little book is very well written, and the author is to be congratulated in his able treatment of some rather difficult subjects. His wording is simple, very clear, and his meaning can be easily understood by those who know little or nothing about the subject of sex.

The instruction given is excellent, and there is nothing in it which might stimulate sex desires.

Parents, teachers, those who are contemplating marriage, and all those who come in contact with sex problems will find this book most valuable.

WM SIDNEY SMITH

CREATING WIDESPREAD INTEREST AMONG PHYSICIANS

VIOSTEROL

is produced with the most complete background of research and control, and is identified by the names of these five eminent American pharmaceutical companies

ABBOTT
MEAD JOHNSON
PARKE-DAVIS
SQUIBB
WINTHROP

The widespread interest shown in this booklet, offered free to physicians on request, is as significant as the material itself. Certainly you will find it worthy of a prominent place on *your* active reference shelf.

Among the conclusions reached in this enlightening document—a reprint from the Bulletin of the Johns Hopkins Hospital of "Calcium and Phosphorus Studies" by Shelling and Hopper—we find that:

"In the average case of rickets treated with moderately large doses of Viosterol, deposits of lime salts may appear at the cartilage-shaft junctions *in as short a time as a week or ten days*." In the severer types

of the disease, the healing period with Viosterol therapy may sometimes be prolonged, but ultimately at least it effects a cure and eradicates the rachitic process completely."

The findings are based on six years' clinical experience with Viosterol preparations in the prevention of rickets, tetany and allied diseases.

ARE NEW DEPARTURES ALWAYS AN IMPROVEMENT ?

NEW methods of manufacture are of interest only insofar as they bring about improvements in the product.

Philip Morris made such a departure by the use of diethylene glycol in place of glycerine, but Philip Morris has proved* that this is a constructive improvement in cigarette manufacture—by producing a cigarette definitely less irritating

In Philip Morris cigarettes only diethylene glycol is used as the hygroscopic agent.

Treatise of 36 Years Close Work With Physicians in Addict Cases

— sent on request from

CHARLES B. TOWNS HOSPITAL

This defines clearly our work with and for the physician — outlines it step by step from the time physician writes us about his alcoholic or drug patient. It shows what specific attentions, what needed emergency methods, are ready at the physician's command, for these mentally baffling cases. Methods—from detoxinizing to mental reconstruction—to returning an individual who cooperates with a will!

For your reference library — detailing the many means — the direction, equipment, environment, at physician's disposal.

STRICTLY
HIGH
CLASS
PRIVATE
SANITARIUM

recognized for 50
years by the medical
profession

Restricted to a limited number of nervous and mental cases—not violent, dangerous, noisy, or otherwise objectionable—with special facilities for the care of aged and chronic cases

Environment and administration are such as affords the most beneficial atmosphere. Contact with others is controlled through caring for the patients in suites (practically all with private baths). A fully qualified medical and nursing staff, physiotherapy, hydrotherapy, massage, and occupational therapy in addition to attractive and modern buildings make "Falkirk in the Ramapos" one of America's most complete sanitariums.

Convenience and accessibility in nearby accommodations and transportation for guests makes the location ideal. The sanitarium and its program of treatment are so arranged that patients have greater comfort and service than found elsewhere.

The School Problem is Vital

The school problem is vital to the parents because they are deeply concerned with the education and training of their boy or girl. It is equally vital to the school authorities because it is their business and life work. School authorities find that parents usually make the great mistake of keeping their boys and girls at home too long. In the first place, just because they love them they tend to humor them, often against their best judgment. Because they love them, they spoil them. A school staff love the boys and girls, too, but in a different and more helpful way, because they do not allow it to bias their better judgment. No amount of coaxing or teasing can make the staff concede to the pupils anything that would be injurious or not for their best interest. The teachers also find that some of the boys and girls have been poorly taught. The educational defects need to be ironed out and corrected, something which cannot, or usually is not, done in the public school.

Again, the school staff aim to co-operate with the parents, just as the patient co-operates with the Doctor in the restoration of health. When you send your boy and girl to a private school have a confidential talk with the teachers and tell them just what you have discovered in your boy or girl that needs encouraging or restraining. If they have any traits that need especial care, it is not only to your interest, but it is your duty to tell the teachers of them in order that they may act intelligently for the pupil's good.

NORTHWEST INSTITUTE

Offering thorough course in clinical laboratory technique, including Basal Metabolism, in 8 months. Also X Ray and Physiotherapy in 3 months. Unusually high graduate placement.

A PROFESSION FOR
MEN AND WOMEN

WRITE FOR CATALOG
3422 E. Lake St. MINNEAPOLIS MINN.

The critical period is not during school hours, but rather in the hours after school and at night when public high school teachers have no chance to guide and lead, to help with lessons. Private school teachers work, eat, play, and live with the boys and girls the entire twenty-four hours of the day. They do their best work in developing characters in the recreation and study hours outside the classroom, a service which the public high school teachers have no opportunity to perform.

Education means the symmetrical development of soul, mind, and body. Neglect of any one of these makes an unfinished man. The most dangerous men in society are educated men whose moral character is deformed, either by nature, which is very rare, or by neglect of early training.

Another aim is to give the mind power rather than attempt merely to store it with information. The power to know is more important than knowing. Recitations are but daily affairs. The ability to think is for a lifetime, and its influence upon others is for eternity.

Vitamin B₁ Therapy in Neurologic Diseases

Both on the experimental side and the clinical side it has been repeatedly shown that vitamin B deficiency leads to severe derangements of the central and peripheral nervous systems, and evidence is rapidly accumulating that such deficiency may be of subclinical grade and cause considerable disability without being recognized. Just what the nature of the bio-chemical changes induced in nervous tissue by vitamin B₁ is, is not clear, although a derangement of glucose metabolism appears to be involved.

'Betalm 1' (Vitamin B₁, Lilly) Pulvules have been found effective in the treatment of alcoholic polyneuritis and other forms of deficiency of this vitamin. They provide for an economical administration of vitamin B₁ to supplement dietary management and are frequently indicated where it is impossible for the patient to assimilate the necessary quantities of this accessory food substance.—*Adv*

Travel and Resorts

Tee Time is All the Time

Golf, the sport for all, is no longer a seasonal game. Wherever you find a little grass and temperature the upper side of the freezing point, you'll find this sport somewhere in the neighborhood of a first class hotel.

Few resorts are without at least one "par excellence" golf course. Once attributed to absentees from "Golf Widows" and to those "slightly erratic," golf has become the sport of males and females from sixteen to sixty-plus.

Golf keeps one out in the open. It offers the finest of opportunities for a mild yet effective exercise. It develops poise, trains the sight and rests the eyes, restores ability to act normally instead of rushing and bustling, takes the edge off harassed nerves (jokes to the contrary notwithstanding), and brings one into association with the finest people.

Pride in a good set of golf clubs is as instinctive as a child's excitement over a new doll, a football, or any toy, and today's crop of "sticks" are as far improved as the 1937 automobile over the gas buggy some of us once used to take us out to the links.

Cost of playing golf, which used to be so prohibitive for the average fellow, is now practically in reach of everyone. Public courses have been largely responsible for this encouraging aspect. A morning or an afternoon at the golf links is no more expensive than running a car for the same period of time—and is decidedly more healthful.

Atlantic City with several fine convenient golf links in its vicinity offers the best time of the year right now, and holds open season for golfers longer than any place of comparative distance from this State.

For those who take their golf seriously, finding time throughout the year in which to take some healthy swings, south Atlantic coast states from Virginia to Florida feature many excellent courses for deep-winter play.

Bermuda, conceded a Treasure Island, holds multiple attractions for the golfer who likes to "play them all" and who enjoys that little sea trip which helps to lure folks to these islands. Without the natural wonders of Bermuda she would still be famous for her golfing facilities. Eight of the finest courses in the golfing world are laid down in Ber-

muda's rolling, wooded terrain, and seven of these are open to visitors. Thousands travel to Bermuda for golf alone, and find themselves amply rewarded by the many other delightful features for the "time out" from golf.

In subtropical regions, over night by fast, luxurious trains of the Atlantic Coast Line, or Seaboard Air line railways, winter is left behind for June-like idealic golfing weather. Practically every town in Florida that receives the attention of northern guests in winter has one or more golf courses which are the equal of the best anywhere, some connected with the finest hotels, others more or less private. In Georgia, North and South Carolina, and Virginia—opportunities to tee off all winter long are open to those who must stay within quick return of home.

With low excursion fares now featured by the railroads, golfing jaunts have become unusually economical, and with tournaments soon wending southward, many golfers will follow their "golfing star" to the greener grasses of winter resorts.

* * *

Let's Fly

The song is gone—but the melody lingers on.

The novelty of flying is fast wearing off and it is becoming "mighty convenient" rather than a sport or adventure. The thrill of moving through space is diminishing and being replaced by the excitement of getting there quicker than our ancestors ever dreamed of.

The past few months have witnessed a tremendous increase in air passengers. Accommodations for weekend schedules have been taxed beyond the capacity of air lines to meet the demand for passages. Thousands have been turned away from terminals and booking offices.

Of course time isn't always such a vital element, but when business or engagements are such that hours saved more than offset a little additional charge, the choice of this mode of transportation becomes almost a necessity.

Airplanes have ceased to be merely a carni-

(Continued on page 252122)

THERE IS

no hay fever

IN BERMUDA

Hay fever causals (see report quoted below) simply do not exist in Bermuda. Nor can they go there, thanks to Bermuda's unique air-conditioning apparatus

This apparatus consists of salt water and a system of prevailing breezes. All air bound for Bermuda must cross a 600-mile stretch of briny deep. En route, even the most persistent ragweed pollen—as well as soot and cinders and taxi-cab honks—must weary and fall, despairing, into the waiting waves. Thus the breeze continues on toward Bermuda in a state of constantly increasing cleanliness.

You, meanwhile, are sunning your complexion on these famous pink beaches. Or perhaps you are splashing in multi-coloured surf, playing golf, tennis, watching the yacht races—anything, in fact, but sneezing!

Bermuda's freedom from hay fever has long been known to visitors. It received official confirmation when Professor Frederick H. Hodgson, in August of 1935, spent several weeks there, under the auspices of the New York State Journal of Medicine, to secure an expert, unprejudiced opinion on the occurrence or absence of hay-fever causals in Bermuda.

"*the Colony,*" stated Professor Hodgson's official report, "*passed a hundred per cent as a sanctuary for hay-fever sufferers*"

"BUT CAN I AFFORD
BERMUDA?"

• The inexpensiveness of a trip to Bermuda always astonishes those making their first visit. Round-trip passage (with private bath) on a luxurious liner costs as low as \$50 for four joyous days at sea. In Bermuda you can secure a splendid room and excellent meals for \$7 a day.

Bermuda
PLEASURE ISLAND

field, Linwood, Somers Point and Seaview. The fall golf tournaments are underway. Each of these clubs reports that the weekends bring a huge influx of golf enthusiasts.

The visiting anglers are returning to the docks with huge catches as the fishing continues good. Boats at the Atlantic City Tuna Club and the Inlet Yachting Center will be making their daily trips to sea or up the back bay as long as the fish continue to bite.

From headquarters of the Atlantic City Camera Contest, Albert H. Skeep, chairman of the committee in charge, emphasizes that the amateur photographers have only until October 17 to submit their summer pictures for consideration.

Chile Celebrates Fourth Centenary of Founding of Valparaiso

Word comes from Chile that in Valparaiso and Vina del Mar elaborate celebrations commemorating the Four Hundredth Anniversary of the founding of Valparaiso began the last week in September and continues through February.

Valparaiso, seventeen days from New York by Grace Line "Santa" ships which make weekly trips down the West Coast, is the chief shipping center of Chile and the port for Santiago, the capital—Valparaiso was founded in 1536 by Juan de Saavedra and named after his birthplace in Spain—a name meaning "Vale of Paradise." Within five minutes' ride from the port, is Vina del Mar, the "Biarritz" of the West Coast—a place of imposing villas, nearby seaside resorts, an ultra modern hotel, and a Casino where fortunes are won and lost in true Monte Carlo style. Both the port and the resort are making extensive preparations for the entertainment of visitors during the period.

The celebration opened with the formal dedication of the new Municipal Theater, new Palace of Justice, and of the Cathedral now under construction in Valparaiso, and a week will be set aside to be known as *Semana del Trabajo*, or "Week of the Workers" during which there will be an Exposition of Industrial Arts and a series of festivals during which native dances and concerts will be presented. Contests will be conducted with awards for the best sculpture symbolic of the history of Valparaiso and for the best essays on the history of Chile.

The calendar of special sports events includes a Chilean rodeo, broncho-busting contests, hockey games, polo matches, soccer, (Continued on page xxxvii)

val ride for amusement seekers—they have become as much a part of daily routine as other things which are taken for granted. We are less excited when someone mentions flying to arrive at their destination, and people are beginning to make a choice of air line companies and their facilities rather than just a decision to go by plane.

Time doesn't "march on"—it flies

"Meeting the Conventions"

During the next few months Atlantic City will more than ever live up to its name of "Convention Capital of America" with thirty major gatherings and a similar number of smaller ones scheduled to come here.

Each year these business sessions bring thousands of the nation's commercial and civic leaders here to participate in three and four day discussions of their various problems. This season is no exception and it is conservatively estimated that in excess of 100,000 men and women will come here for this purpose during October, November and December.

The convention program got off to a good start with the arrival of delegates from all over the country to attend the annual meetings of five allied groups in the baking industry. These include the American Bakers Association, Bakery Equipment Manufacturers Association, Millers' National Federation, Allied Trades of the Baking Industry and the National Association of Bakery Supply Houses. Approximately 10,000 delegates all told attended the sessions which were held in the municipal convention hall.

Following closely on the heels of the bakers there comes a long list, led by the 25th annual Safety Congress and Exposition, October 5 to 9, another gathering expected to attract in the vicinity of 10,000 delegates. After that come still other groups continuing right up to the next summer season and keeping Atlantic City constantly on its toes catering to the varied tastes of its guests.

With the many visitors here a variety of diversions is provided for them. In October the beach is thrown open to equestrians and a fine bridle path, a wide flat stretch eight miles long, will be available. Meanwhile mainland bridle paths, particularly attractive at this time of the year, continue popular. The Boardwalk bicycle lane, open from 6 a.m. to 9 a.m., is getting its usual large quota of cyclists each day. The 'walk provides what is probably the safest bicycle lane in the country.

On the nearby courses at Brigantine, North-

rugby, football, gymnastic drills, bicycle races, and swimming contests. The celebrations will end with an International Horse Show and a week of carnival.

Invitations have been extended to many foreign countries asking them to send military teams to represent them at the horseshow and according to the newspaper "El Mercurio," a gratifying number of acceptances have been received. It is expected that teams will be sent from the United States and Canada.

* * *

Train Travelers Soon to be Able to Ship Their Cars Between Canada and U S

Effective Oct. 15, private automobile owners can ship their cars not only between points in Canada, but also from Canada to the United States, under a new "passenger-with-automobile plan" announced here by C B Foster, Passenger Traffic Manager of the Canadian Pacific Railway. Under this plan, owners at very moderate expense can eliminate long distance drives, and may secure prompt delivery of their automobiles at their destination.

In formulating the plan, the Canadian Pacific Railway realized that a great many car owners want their machines when sight-seeing, but object to driving the intervening distance to reach resort territory. The plan provides for shipment of a car in freight service at a rate equal to one and one-third times the one way first class passenger fare, provided the car owner also holds two first class tickets covering the journey. Thus a man and his wife, desiring to go to Vancouver, could have their car shipped via freight by presenting their passage tickets, and paying a further fare and one-third for their automobile. Further, passengers enjoy all privileges, including alternative routes.

The "passenger-with-automobile plan" provides a minimum delay in receiving cars at destination. In fact, if the cars are shipped in advance, they should reach their destination almost as soon as their owners. Stopover privileges for cars are also included, and a further feature in the case of shipments to the United States is the simplicity with which the Customs regulations have been worked out. Under this plan the owner will not have to be present when the car passes the Customs.

The new service extends to cars shipped by freight to seaports for shipment overseas, and in the case of through shipments includes carriage on the "Princess Helene" across the Bay of Fundy to Nova Scotia and on the British Columbia Coast ships between Vancouver, Victoria and Seattle.

"Brains" of Ocean Liners

You've often heard of the gyro-compass, the "Metal Mike" and all of the other gadgets which go to make up the "brains" of a modern transatlantic liner but have you ever stopped to wonder about them and just what purposes they serve?

Your correspondent has!

So we decided to find out about them in a language we could understand. Once this decision was reached, we immediately hied ourselves to the bridge—that "no passengers permitted" land of any vessel—of the new Cunard White Star super-liner "*Queen Mary*" when she was in port the other day to get all of the details on the most modern navigation instruments.

The first person we ran into was Junior First Navigating Officer Harold P. Grindrod. He said he'd be glad to explain the bridge instruments to us and spent a half day doing so. At times Mr. Grindrod's language got a little too technical, but our blank looks managed to bring him back to terms we could understand. The following is a faithful record of his explanation of the myriad instruments on the bridge.

Gyro-Compass—This is a mechanical compass, the principle of which was adopted from the gyro top we all played with as children. It is a wheel weighing sixty pounds and revolves at the rate of 6,000 revolutions per minute. This compass always points to the "true North" as it gets its directive force from the earth's rotation and the force of gravity. This is perhaps the most important instrument on the bridge.

Gyro Pilot—This is an automatic steering device, known in navigating parlance as "Metal Mike." When this instrument is connected to the gyro-compass, the navigating officer can set it on any course he wishes to follow and the vessel will follow that course without deviation or human operation. By merely moving a lever on the steering apparatus of this instrument it can immediately be changed from automatic to hand steering.

Telemotor Gear—There are two of these aboard the *Queen Mary* and they are used for hand steering. They operate hydraulically. This gives the *Queen Mary* three complete sets of steering gears—the duplicate hydraulic telemotors and the electric telemotor system incorporated in the gyro pilot, which is a parallel system.

Bearing and Steering Repeater Compasses—There are two bearing repeaters, one on

each wing of the *Queen Mary*, which are used for taking bearings from either the sun or land. The steering repeaters are located inside the pilot house, one atop the gyro pilot, and also are used for taking bearings and celestial observations. These also are auxiliaries of the gyro-compass.

Magnetic Compass—This supplements the gyro-compass for taking bearings. It is similar to the old style compass as first carried on ships. The magnetic compass gets its directive force from the earth's magnetism and therefore points to the "magnetic North" instead of the "true North."

Course Recorder—Every movement of the ship's head is shown on a graph contained in this instrument. It shows an alteration of one degree variation from the set course. This also is connected to the gyro-compass.

Electric Telegraphs—These are the most modern means of signalling the two engine rooms and have replaced the old style chain and gearing telegraphs. They are built in pairs, one telegraph for the engines operating the two starboard (right) propellers and the other for the port (left) propellers. There is a set on the starboard open bridge, another on the port open bridge and four in the navigating room. When the liner is in port, the handles stand at the word "stop" on the face of each instrument. The face is divided into two sections, "astern" and "ahead" and the orders read "finished with engines," "dead slow astern," "slow astern," "half astern," "full astern," "stand by," "dead slow ahead," "slow ahead," "half speed ahead" and "full speed ahead." The navigating officer moves the handle to the desired order and a handle on a similar instrument in the engine rooms moves to the same order, a bell ringing at the same time. The engineer then signals the bridge on the same instrument that he has received and is carrying out the order.

Helm Indicator—This instrument indicates whether the liner is keeping a true course. If the helm (front of ship) moves to port (left) of the course set on the compasses a red light shows, if to starboard (right) a green light.

Silent Room—A small room about three times the size of an ordinary telephone booth, located in one corner of the wheelhouse. This room contains the submarine signaling devices. Each lightship has its own call. So many strokes, according to the lightship, are sounded by means of a submarine oscillator. By clamping ordinary telephone receivers to each ear, the navigating officer is able to hear the strokes. By locating on his chart the

lightships from which he is receiving the signals, he is able to ascertain his true position.

Distance Indicator—This instrument is worked in conjunction with the ship's wireless and is used for ascertaining the distance from any given lightship.

Direction Finder—This is an instrument for receiving signals from various land stations and lightships. Each station has its own distinctive call. The man operating the direction finder aboard the *Queen Mary* turns his dial until he has tuned in a certain station call at its strongest point. He then tunes in another station until he is receiving the call as strongly as possible. Next he takes his chart and draws lines from the stations to the positions where he received the signals. The position of the *Queen Mary* is where these two lines cross on the chart.

Fathometer—Twenty-four times a minute this instrument records on a graph the depth of the ocean bed beneath the ship's keel. It is entirely independent of any other instrument. Recordings are made by means of sound. A transmitter, somewhat like a hammer, sends sounds through the ship's skin (hull) to the bottom of the sea. These sounds, or echoes, are picked up by another instrument on the ship known as a hydrophone. The depth recording is made by instruments which measure the time it takes for the echo to return to the ship. This instrument takes the place of the old lead soundings, and eliminates any chance of human error, as well as giving more frequent readings. However, the hand line also is used on this vessel when the navigating officer wishes to ascertain the type bottom—whether it is sand, gravel, mud, etc. Particles from the bottom adhere to soap in a cavity in the bottom of the lead weight.

Revolutions Indicator—There are four of these and they indicate the revolutions per minute of each of the four propellers.

Hydraulic Door Closer—This instrument shows the location of all water-tight doors on D and E decks. During foggy and dangerous weather these doors are all closed from the bridge by means of this instrument. It rings a bell at each location to indicate the door is being closed, and a red light shows on the diagram when it is closed. If this door is opened, the bridge is immediately informed when the light goes out. However, all doors can be opened by hand and will close automatically again when the instrument is in operation.

Siren Buttons—These are used to sound the three giant sirens, which can be blown singly or in unison, according to the button pushed. A fourth button is for automatic sounding.

t. i. d.

"Three times a day" does not have to be prescribed for guests of the Flanders—for no one who has ever sat down to a meal here, ever neglects his "t. i. d." But it's not the excellent food alone that makes this the outstanding family hotel of the "World's Playground"—beds like those at home, comfortable places to lounge indoors and out, and friendly types of guests both young and old, also help make it the preferred seashore hostelry. As convenient to all points of interest as it is to all vacation budgets. Same family management 35 years

AT THE FLANDERS ATLANTIC CITY

During fog, this button is pushed and causes the sirens to sound every five seconds. It also causes steam to be ejected from the sirens to show other vessels where the sound is emanating from.

Electric Anchor Telegraph—This is used to signal the seamen to hoist or lower the anchor.

Stern Bridge Telegraph—This instrument is used to signal the officer on the stern bridge when the liner is pulling into or backing out of her dock.

Ship's Telephone—This is connected to the stern bridge, crow's nest, forward (front) and after (back) decks, forward mooring space

and to other parts of the ship to give necessary verbal orders.

Navigation Lights Indicator—This is a large glass enclosed in a frame and shows the position of the masthead, green starboard, red port, and after mast stern lights. If one of these fails a bell starts ringing and shows which light is out.

Clearview Screen—This is a circular glass fitted in the forward windows of the bridge. During fog, rain or snow the navigating officer starts this glass revolving by means of a high speed motor. Its speed throws every-

Petrolagar
Plain

For the relief of constipation, Petrolagar is a palatable emulsion of pure liquid petrolatum (65% by volume) and number one silver white kobe agar-agar accepted by the Council on Pharmacy and Chemistry of the American Medical Association for the treatment of constipation.

ACCEPTANCE

The acceptance of Petrolagar by the Council on Pharmacy and Chemistry of the A.M.A. as well as the acceptance by the medical profession generally, is a tribute to its clinical efficiency. Petrolagar Laboratories, Inc., Chicago

Petrolagar is a palatable emulsion of pure liquid petrolatum (65% by volume) and number one silver white kobe agar-agar accepted by the Council on Pharmacy and Chemistry of the American Medical Association for the treatment of constipation.

ACID RESISTANCE

WITH

KALAK

Hypertonic—Alkaline—Carbonated—Not Laxative

The years of experience with physicians who have used Kalak show that the use of a formula containing calcium, magnesium, sodium and potassium salts represents a correctly balanced solution. This is Kalak which, as such, aids in maintaining a balanced base reserve.

How Alkaline Is Kalak?

One liter of Kalak requires more than 700 cc. N/10 HCl for neutralization of bases present as bicarbonates. Kalak is capable of neutralizing approximately three quarters its volume of decinormal hydrochloric acid.

Not the Occasion for Compromise

WHEN THE new mother has passed through the first two stages of labor—her strength expended and her physical resources at an ebb—the outcome of her pregnancy must not be compromised. Observing every precaution, the experienced physician chooses his pituitary extract with care.

PITUITRIN, the Parke-Davis solution of posterior pituitary U S P is the *original* commercial pituitary extract. The greater portion of the clinical data reported in the literature has been based on this preparation.

BECAUSE Pituitrin served to introduce pituitary extract to the medical profession, and because of its subsequent wide-spread use, the name is occasionally misapplied to other pituitary products. Be certain that Pituitrin (which is prepared only by Parke, Davis & Company) is supplied on all requisitions. Specify "Pituitrin, P D & Co."

PARKE, DAVIS & COMPANY

THE CAMP TRANSPARENT WOMAN

IT IS our privilege to present, as our contribution to public health education in America, the Camp Transparent Woman—an exact life-size reproduction of the female body, with every organ, blood-vessel and bone clearly visible. Before going on a transcontinental tour, this figure is being shown to the general public at the New York Museum of Science and Industry, where leading medical and health authorities attended its recent premiere.

It is our earnest hope that the Camp Transparent Woman will increase woman's knowledge of her physical self and foster a more enlightened attitude toward the advice of the physician.

More Unsaturated Fatty Acids...

ANALYSIS

UNSATURATED FAT CONSTITUENTS

Determined by Iodine Absorption
(Hanus Method)

- 1 Evaporated Goat Milk
Iodine Number 39.06
- 2 Evaporated Cow Milk
Iodine Number 33.06

- 1 Test made by Truesdail Laboratories, Inc., Los Angeles
- 2 Test made by Hunzaker and Spitzer, reported by the Indiana Agricultural Experimental Station, Bulletin No. 134

The disclosure that Meyenberg Evaporated Goat Milk contains approximately 20% more unsaturated fatty acid compounds as compared with evaporated cows' milk is important. Dr. W. McKim Marriott, in his recent book "Infant Nutrition," page 61, states "Recent observations would seem to indicate a relationship between deficiency of unsaturated fatty acids in the diet and some cases of infantile eczema."

The pure, sterile, standard quality of Meyenberg Evaporated Goat Milk makes its use advisable when prescribing special formulae for difficult feeding cases. Available in 14 oz. size can (makes approximately one quart when diluted with water). SOLD by high-grade grocers and pharmacies everywhere.

EFFECTIVE... ECONOMICAL

The question of effectiveness is uppermost in the mind of the physician

"Benzedrine in a 1 per cent oil solution gave a shrinkage which lasted approximately 18 per cent longer than that following application of a 1 per cent oil solution of ephedrine"

—Giordano Penno Med J, Oct 1935

But economy to the patient is also important

Benzedrine Solution is one of the least expensive of liquid vasoconstrictors. And, when low first cost is coupled with lasting effectiveness, the economy is obvious.

BENZEDRINE SOLUTION*

For shrinking the nasal mucosa
in head colds, sinusitis and hay fever.

*Benzyl methyl carbinamine 1% in liquid petrolatum with $\frac{1}{3}$ of 1% oil of lavender

Control of Type I and Type II Pneumonias with

ANTIPNEUMOCOCCIC SERA

Lederle

SUCCESS IN THE SERUM TREATMENT of lobar pneumonias is measured by

- a 60% reduction in the death rate of Type I cases
- a 40% reduction in the death rate of Type II cases
(if injected within 96 hours of onset)

Specific antipneumococcic sera offer the only certain means of reducing the death rate in Types I and II pneumococcus pneumonias—the cause of nearly 50% of all adult lobar pneumonias between the ages of five and fifty

"The Massachusetts Pneumonia Study, under the auspices of the State Department of Health has demonstrated that specific treatment can be successfully used by physicians in general practice. Over nine hundred patients with lobar pneumonia have been treated by nearly four hundred physicians."

Success is largely dependent upon prompt bacteriological diagnosis facilitated by the Neufeld Rapid Typing, early and adequate treatment, and of equal importance—the use of serum of the highest quality

Refined and Concentrated Antipneumococcic Serum **Lederle** represents the accrued knowledge gained by years of experience in its manufacture

- "Lobar Pneumonia and Serum Therapy" by Frederick T. Lord and Roderick Heffron, published by The Commonwealth Fund in 1936

Proctologists

THE YEOMANS' PROCTOSCOPE is an ideal examining and operating instrument, providing direct illumination, light rays focused at the distal end. The light carrier fits accurately into the auxiliary tube with only the lens projecting into the main tube. The vision of the observer and the path for the introduction of instruments for examination, local applications or operation is always clear, there being no obstruction in the tube.

The entire instrument may be carried in the physician's bag and for this reason is supplied without a case. All parts of the instrument which come in contact with the patient may be sterilized by boiling. The Yeomans' Proctoscope complete with 10" x 3/8" tube, obturator, light carrier, conducting cord, lens cap, lamp and inflation bulb sells for **\$33 50**

Other size tubes are available in this set including, infant and sigmoidoscope.

Yes! Every Cow has a History Record

**Certified by
Competent
Veterinary
Authority...**

EVERY Dairylea cow is physically examined and a health record certified by competent veterinarians—men who are approved by both state and city health departments. More, a *second record* is kept . . . attested to by Dairylea field inspectors . . . giving specific information on 79 points regarding environment, care, health of

handlers, and sanitation in the handling and housing of milk

At the source and all the way to the doorstep of the consumer, Dairylea Milk is inspected and protected well beyond the requirements prescribed in health regulations. You can unhesitatingly recommend Dairylea Milk and Dairylea Milk Products as foods produced under strict sanitary supervision

DAIRYLEA

Our Pledge: We, the farmers of the Dairymen's League, recognize a definite obligation to the public. Since milk is nature's most nearly perfect food, we pledge ourselves, in the production of Dairylea Milk Products, to do everything within our power to safeguard their purity and quality

**The Dairymen's League

milk

one of the important alkaline-ash foods

To maintain the proper acid-alkaline balance of the system, it is essential that sufficient alkaline-ash foods be ingested to neutralize the total acidity of metabolism

Milk, green vegetables and fruits are three of the most valuable alkaline-ash foods because of their rich Calcium, Sodium and Potassium salts content.

Increased ingestion of milk is, therefore, a good and convenient way to maintain the alkaline-ash content (or alkaline reserve) of the blood *The Bureau of Milk Publicity, Albany*

THE STATE OF NEW YORK

Hundreds of TONS of DUST

fall yearly on each square mile
of large cities

A shockingly large amount of dust—literally hundreds of tons—is deposited annually over each square mile of the larger urban centers. The following figures, from independent studies made over a period of years, are not isolated examples but typical of the atmospheric pollution in large cities.¹

	Tons of dust per sq. mi. annually	In many smaller communities even worse conditions may prevail under any of the following combinations: (1) soft coal, (2) low inland wind velocity, (3) concentrated manufacturing activity, (4) no zoning regulations, (5) no smoke abatement ordinances.
Baltimore	1800	
Pittsburgh	1031	
Salt Lake City	349	
Cleveland	780	
Washington	291	

It is noteworthy that even a nonindustrial city such as Washington has so high an atmospheric pollution, due mainly to smoke from residences and office buildings. This vast amount of soot and dust cuts off light. Shrader, Coblenz, and Korff, for instance, found that the amount of ultraviolet light in Baltimore was half that 10 miles from the center of the city.¹ Under such circumstances, to rely on winter sunbaths for the treatment of rickets may prove ineffective.

a dependable antiricketic OLEUM PERCOMORPHUM

Price Substantially Reduced Sept. 1, 1936!

At a cost to the patient of less than 1 cent a day you can prescribe 1,000 vitamin D units of Oleum Percomorphum, a dose regarded as adequate for the prophylaxis of rickets. At no additional cost the patient receives at least 7,000 units of vitamin A. Furthermore, the natural vitamins A and D in Oleum Percomorphum are in the same ratio as in cod liver oil* but in 100 times the potency. Each gram supplies not less than 60,000 vitamin A units and 8,500 vitamin D units (U.S.P.). This means that the time-tried benefits of cod liver oil without its necessarily large dose are available even to premature and young infants, who are often most in need of antiricketic therapy. Supplied in 10 and 50 c.c. bottles and 10-drop capsules (boxes of 25 and 100).

Crookes

Every physician will want to read the new 84-page catalogue just issued by the Crookes Laboratories. It is full of interesting information on colloids in medicine. Keep abreast of this modern form of therapy. If you have not already received it, send for your free copy today!

Crookes first introduced Colloidal Silver (Collosol Argentum) over thirty years ago. Since then over 350 published references in the literature attest to the efficacy of Crookes colloids and pharmaceutical specialties. Every modern scientific means is used in the huge Crookes Laboratories to assure uniform physical and therapeutic excellence. "When it comes to Colloids—come to Crookes."

CROOKES LABORATORIES, INC., 305 East 45th St., New York, N. Y.

"MASTER" ELASTIC STOCKINGS

**Backed by More Than 65 years
of Experience and Service**

Uniform pressure is absolutely essential in an elastic stocking to secure correct support and restore normal circulation. Uniform pressure can only be secured by hand-woven stockings. Pomeroy "MASTER" Elastic Stockings have always been hand knitted, woven (not cut), to shape. "MASTER" Stockings are also made with either pull straps or longer side straps as desired. Women are always delighted with the invisibility of these stockings thru even the sheerest silk hose. The "MASTER" is widely preferred for both effectiveness and economy.

In prescribing elastic stockings protect your patient all the way—prescribe the type of stocking required, prescribe the stocking you know will do its duty, prescribe where to buy—prescribe POMEROY.

RY-KRISP *for* Common Constipation

The beaker at the left contains one dry Ry-Krisp wafer, crumbled. At the right is the same quantity of saturated Ry-Krisp—showing what happens when the liquids in the stomach come in contact with it. Each wafer absorbs five times its weight in water, producing bulk to stimulate peristaltic action.

BECAUSE it is a tempting, highly palatable food which patients are glad to eat regularly, many physicians find Ry Krisp ideal as a natural corrective for common constipation due to insufficient bulk.

Made simply of whole rye, salt and water—double-baked to tempting, brittle crispness—Ry-Krisp has a high percentage of bran, high pentosan and crude fiber content—all of which encourage normal bowel action. Moreover, its low water content (only 6.8%) and porous structure permit each wafer to absorb five times its own weight in water. This produces needed bulk to stimulate natural peristaltic action.

The very fact that Ry-Krisp is such a pleasant alternate for crackers, toast or bread—at breakfast, lunch or dinner—is assurance of satisfactory results in the diet. Your patients—both children and adults—are glad to eat these crisp, whole rye wafers regularly.

For free samples and the Laboratory Research Report on Ry-Krisp, use the coupon below.

VITAMINS IN CANNED FOODS

V. VITAMIN G

● By 1926, it was apparent that the anti-neuritic vitamin B of earlier investigators was in reality a combination of several vitamins. In that year, Goldberger postulated the existence of a second vitamin associated with the so-called vitamin B "complex" which he designated as the P P or pellagra preventive factor. Evidence has been offered that this factor—subsequently named vitamin G—exerts a specific action in the cure and prevention of human pellagra and a similar condition in experimental animals (1).

Since Goldberger's pronouncement, considerable research has been devoted to resolution of the vitamin B complex and, what is equally important, to testing the specificity of vitamin G in the cure of human pellagra (2).

The findings in the laboratory and clinic have not, in some respects, been entirely in accord (3).

As reports of further investigations appeared in the literature, it became clear that the vitamin B complex had been aptly named. At one time claims were made for the existence of as many as eight factors in this complex (4).

While later work has reduced this number, we know today that what has been considered in the past as vitamin G is, in

reality, a combination of several factors. A relation between experimental cataract and vitamin G has been described and, recently, another associated factor was postulated (5).

The significance of these individual factors in human nutrition has not as yet been established. However, regardless of this fact, students of nutrition are agreed that we must provide for the inclusion of so-called vitamin G—admittedly a complex—in the daily dietary. It is also obvious that until more is known about the individual components of the complex, we must continue to depend upon present day bioassay methods to determine the "vitamin G" potencies of foods.

In this connection, many canned foods have been found by comparative studies to retain their original vitamin G potencies as measured by methods now in common use (6).

Investigators in the U S Public Health Service have described their values in the control of human pellagra (7).

Commercially canned foods, therefore, may be used with confidence that they will supply amounts of vitamin G consistent with the amounts present in the raw food materials.

A better hearing aid made to individual requirements

The RADIOEAR

The Selux A-Phone is a new scientific invention which is intended to enable the medical profession to render a further service where the impairment will not respond to treatment. An analysis with this instrument determines the characteristics that must be built into each individual hearing aid. This goes to the laboratory and the hearing aid—THE RADIOEAR—is built with the characteristics shown by the analysis.

The RADIOEAR is an acoustically balanced instrument with proved scientific principles made to the specific analysis of the degree of hearing impairment of each individual. A comfortable efficient and highly perfected hearing aid.

SEX BEHAVIOR IN MARRIAGE by CHARLES A. CLINTON, MD

AT last a book of sex technique that treats the subject frankly and in detail without offending. A medical authority proves that it is possible to cast aside all pretense and false modesty and discuss the most important single factor in human life in an intelligent, instructive manner

SUBJECTS DISCUSSED

The Organs of Sex • Choosing the Proper Mate • The Wedding Night • The Technique of the Sex Act • The Various Stages of Sexual Union • Advantages of Various Positions • Impotence and Frigidity • Frequency of Intercourse • Sex Taboos • Birth Control

ALSO SUITABLE FOR THE LAYMAN

Here is sincere and discerning advice on the intimate details of conjugal behavior. The new and startling revelations in this book will show the young married couple how to protect themselves from the intricate results of abused emotions. Dr. Clinton has given in revealing yet dignified manner correct instructions for the proper method of performing the sex act. A book any physician can recommend wholeheartedly to those of his patients suffering from sexual maladjustment.

It is the purpose of this book to give exact instructions for marital procedure. Dr. Clinton's long years as a physician and wide clinical experience merit your confidence.

Your name and address on margin brings you this valuable book C.O.D. Pay postman \$2.00 plus postage. Money back in five days if not satisfied.

**TREATMENT OF SYDENHAM'S CHOREA WITH TYPHOID
PARATYPHOID VACCINE**

DONALD WEISMAN, M D and CHARLES LESLIE, M D, *New York City*
New York Post-Graduate Medical School and Hospital, Department of Pediatrics

Introduction

The treatment of Sydenham's chorea by means of the intravenous injection of typhoid paratyphoid vaccine has caused much discussion in recent years. There has been some difference of opinion in regard to the efficacy of the method, its apparently unpleasant nature, and its dangers. We have analyzed the effects of this treatment on fifty rather severe cases and present an evaluation of the therapy. A comparison with seventy-five cases treated on this service with miscellaneous methods, and a review of other treatments are included.

Historical

The abrupt cessation of symptoms when a choreic child contracted an intercurrent acute febrile disease has been occasionally commented upon. It was mentioned as early as 1818 by Nathaniel Chapman.¹ Turnovsky² (1930) witnessed a case of chorea which was cured by intercurrent typhoid fever. There have been several reports on the treatment of chorea by intramuscular milk injections with varying success, notably Kern,³ Hymanson,⁴ and Somogyi.⁵ Mas de Ayala⁶ inoculated a child with *Treponema* *Hispanicus* who had had chorea for two years, thus producing experimental relapsing fever. The child was well after four febrile episodes.

Sutton,⁷ working independently, induced high temperatures of short duration by the intravenous injection of typhoid paratyphoid vaccine. There was

striking success, and Sutton and Dodge⁸ reported in detail on 150 cases treated in this fashion. The average duration had been shortened for all degrees of severity of chorea and the percentage of cures was high. (The term "cured", as used in this paper, applies to a single attack.)

Material and Methods

The subjects of this series were fifty children with moderately severe to violent chorea. More than thirty children with mild symptoms were not accepted for the vaccine treatment for several reasons. *First*, it is usual for mild symptoms to subside slowly with rest and sedatives alone, and therefore it was felt that these cases did not provide a sufficiently rigorous test of the efficacy of the method. *Second*, although Sutton and Dodge had recommended vaccine treatment for mild cases with the hope of aborting subsequent severe symptoms, very few of our mild untreated cases became more severe. We did not therefore consider it justifiable to submit these mild cases to a somewhat drastic therapy.

The moderate group (16%) comprised children who had fairly constant purposeless movements, beginning dysarthria, and grimaces.

The severe group (76%) consisted of children who had marked dysarthria and severe incessant movements, they were unable to feed themselves and exhibited frequent facial contortions.

The violent group (8%) were children who were considered equal to the most

The severe group (76%) consisted of children who had marked dysarthria and severe incessant movements, they were unable to feed themselves and exhibited frequent facial contortions.

The violent group (8%) were children who were considered equal to the most

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 28, 1936*

violent cases the staff had ever seen. They could not speak, purposefully hold their arms in any position, or grasp an extended object. They writhed in their sleep. We were concerned with the possibility of these children injuring themselves.

Artificial hyperpyrexia of 105° - 107° F was induced by the intravenous injection of the vaccine. Until the disappearance of the chorea, this was done daily, except for visiting days and for times when other demands upon our nurses made it advisable to omit treatment for a day. In our experience, temperatures under 107° F were not dangerous, however, those which exceeded 107° were invariably amenable to simple measures.

Only one temperature rose to alarming heights, this reached 109.2° but thirty-five minutes later, following remedial measures, it had dropped to 104.6° and then steadily down to normal. There were no ill effects discernible. This occurred in an early case and took place because too little attention had been focused upon the significance of chills which always signify a rapidly rising temperature.

Hench⁹ reported on 10,000 intravenous injections of typhoid paratyphoid vaccine in about 2,500 patients. His patients were adults, far less thermolabile than children, and without the recuperative powers of children. They were the subjects of vascular diseases, arthritis, etc. His doses were smaller than ours and the temperature lower, yet some degree of protein shock was obtained. He had only three deaths, a rate of .03 per cent for the 10,000 injections. The incidence of complications was 0.5 per cent for the 10,000 injections, and the complications were appendicitis, cholecystitis, glaucoma, iritis, pericarditis, pleurisy, and similar conditions. These do not seem to us to have been related to the therapy.

Wright and his co-workers have given over 5,000 intravenous injections of typhoid paratyphoid vaccine, over a period of about five years, to adult patients with vascular disease. They comment upon the fact that these patients had very fragile vascular trees compared to our children, and that many of them had phlebitis before the start of treatment. As in

Hench's cases, the doses given were very much smaller than those we used and the resulting protein shock less severe. Yet here again, definite protein shock was the desideratum and was generally obtained. They state that ordinarily about thirty per cent of thromboangitis obliterans cases of long standing develop the anginal syndrome with or without true coronary thrombosis if untreated. It is significant that only two of their cases of thromboangitis obliterans manifested acute symptoms of coronary occlusion following the vaccine. In each instance, the coronary symptoms developed more than twenty-four hours after the return of the temperature to normal. Both of these cases had had previous attacks of acute coronary thrombosis. Wright and his co-workers admit the possibility of these incidents being due to the vaccine but feel that it is highly questionable that the vaccine played a real part. There were no other complications or deaths.

It is true that smaller doses than ours were used and lesser degrees of protein shock obtained in these two series of 15,000 injections. Nevertheless the figures are of great interest to us because the difference in patients makes the figures comparable. If we can raise the temperature of an adult with, for example, generalized arteriosclerosis and coronary disease to 102° - 104° F, then surely a child, with a comparatively elastic vascular tree and enormous recuperative powers, may safely have its temperature raised one to three degrees further.

Although the high temperatures which we achieved (105° - 107°), may seem alarming, we have had no complications or deaths, and there are but few authors who have encountered or attributed such occurrences to the intravenous vaccine.

Sutton and Dodge established the basic points of this procedure. We followed their rules as to dosage, nursing, and convalescent care with but few changes. A description of the technic is to be found in the report by Sutton and Dodge.⁸

However, two important deviations from the routine of Sutton and Dodge may well be noted. First, as discussed previously, we placed great emphasis upon the occurrence of a chill as indicating a rapidly rising temperature. The temperature was recorded every five minutes

during and following a chill until the sharp surge of mounting hyperpyrexia was over. We consider this practice to be an important safeguard.

Second, we gave large doses of sodium amytal (G 0.1-0.2) by mouth about two hours before treatment each morning. Sodium amytal was resorted to because the main objection to the vaccine treatment was that the children were uncomfortable during the period of hyperpyrexia. It was deemed necessary to alter the original technic so as to make it acceptable to the children. The sodium amytal itself probably had little if any influence upon the duration and the course of the chorea. Several children were given sodium amytal alone for six or seven days with but little effect. In addition, it will be emphasized later, in the discussion of the treatment of chorea by means of miscellaneous methods, that sedatives have not in the past been found to be of any particular value.

The sodium amytal rendered the patients less apprehensive and quite drowsy during the high temperature period. The children were made fairly comfortable and rarely objected to the treatment. They often asked "to have one more treatment, just to make sure."

We felt that the only contraindications to this therapy were concomitant conditions so severe as not to permit a patient to stand the strain of so high a temperature without danger, for example severe anemia, extreme malnutrition, cardiac decompensation, etc. Cases of active carditis with good cardiac function were treated.

Outline of Treatment

A—Material New York City typhoid paratyphoid vaccine or its equivalent is used. This preparation contains 1,000 million B typhosus, and 750 million each of B paratyphosus A, and B paratyphosus B in each cubic centimeter. The vaccine is boiled for three minutes to ensure sterility before it is used the first day, and thereafter kept in the icebox. The Lot Number should be noted carefully, the same child should always receive the same Lot Number.

The vial should be shaken vigorously before each withdrawal of vaccine. Dilution of this material for the purpose

of more accurate dosage is found clinically to be unnecessary.

Standard tuberculin syringes are used for injection. One can easily estimate differences of 0.005 c.c. Use 24G / 3/4" needles.

B—Dosage The initial dose is always 0.05 c.c. undiluted vaccine, intravenously. It is wise to proceed cautiously for the first few days so as to "feel out" the thermolability of the individual patient. Children vary greatly in their degree of reaction to the same dose.

Tolerance to the vaccine increases with each day's treatment in the large majority of cases. A dose that produces today the satisfactory temperature of 105° will, in all probability, produce only the unsatisfactory temperature of 103° tomorrow. Therefore the dosage must be constantly increased in accordance with the patient's previous reactions.

For example with dose of 0.05 c.c., if temperature goes to 105°, give 0.08 c.c. next day, if 104°, give 0.10 c.c. next day, if 103°, give 0.13 c.c. next day.

With dose of 0.10 c.c., if temperature goes to 105°, give 0.13 c.c. next day, if 104°, give 0.15 c.c. next day, if 103°, give 0.20 c.c. next day.

After the first day, a second dose or even a third is given on the *same* day if the temperature with the first dose *remains stationary* for two consecutive readings at less than 104°. This must be injected promptly so as to act as in Fig. 1a and not as Fig. 1b.

Fig. 1a

Fig. 1b

For example With initial dose of 0.20 c.c., if temperature levels at 101°, give an additional 0.20 c.c. With initial dose of 0.20 c.c., if temperature levels at 102°, give an additional 0.15 c.c. With initial dose of 0.20 c.c., if temperature levels at 104°, give an additional 0.05 c.c.

Further, if temperature goes to 105° with 0.20 c.c.+0.20 c.c., give 0.5 c.c. the next day as an initial dose. If temperature goes to 104° with 0.20 c.c.+0.20 c.c., give 0.55 c.c. the next day as an initial dose. If temperature goes to 103° with 0.20 c.c.+0.20 c.c., give 0.6 c.c. the next day as an initial dose.

The calculation of secondary dosages and subsequent day's dosages depend also upon the speed of the child's reactions. A slowly reacting child tolerates a relatively larger dose than a quickly reacting child, mainly because there is more ample warning of excessive rise and greater time in which to check it if desirable.

Subjects of repeated attacks generally require larger doses of the vaccine to produce a satisfactory change in temperature.

C—Routine nursing orders

1 High caloric and high vitamin breakfast and supper

2 No visitors during treatment, room darkened and quiet.

3 Breakfast at about 6 30 A M

4 Sodium amytal, gr $1\frac{1}{2}$ -3 by mouth after breakfast. The dose is reduced after the first few days.

5 Vaccine intravenously at about 8 30 A M

6 Hot-water bottles and blankets immediately after the vaccine. The blankets are merely placed on top of the bed since it is well-known that blanket packs alone can produce a considerable temperature rise. Therefore bundling or packing the child with the blankets are to be carefully avoided.

7 Temperature recorded stat.

8 Codeine in large doses (gr $\frac{1}{2}$ -1) subcutaneously fifteen minutes after the vaccine. It is given in the leg to avoid a sore arm around which a tourniquet must be wrapped at the subsequent treatment. The codeine is timed to act most effectively when the expected nausea, headache, and chill arrive, which is usually about twenty-thirty minutes following the vaccine. These unpleasant symptoms are most in evidence the first and second days. There may even be slight emesis the first day. They are of very short duration however, rarely disturbing the child for more than a half hour. A smaller dose of codeine is given later if the unpleasant symptoms have not subsided. After the first few days the codeine may be given by mouth just after the vaccine is administered, or may be omitted. Aspirin is contraindicated since it is an antipyretic. The amytal and the codeine act synergistically to control the discomfort. Indeed, children commonly sleep through the treatment, waking only when aroused by the temperature taking.

9 Fluids are limited during treatment to small pieces of cracked ice, or sips of plain water, carbonated water, or lemonade.

Large amounts of fluid cause a sudden fall in the temperature.

10 Temperatures must be taken with great care at the following times: each half hour to 103° ascending, each quarter hour from 103° ascending and descending, each half hour descending below 103°, each one hour descending below 102° until normal for two hours.

11 Notify doctor at once re all temperatures and chills.

12 Take temperatures *each five minutes* after chills until otherwise ordered.

13 When temperature has dropped to below 104°, remove blankets and give fluids freely. Children undergoing treatment generally have poor appetites but they usually are thirsty, so it is best to take advantage of this by giving orange juice with added sugar instead of plain water, thus aiding their nutrition.

14 When the temperature has fallen to about 101°, give the patient a tub bath and remake the bed. The fresh linen and the clean feeling make the children happy and cheerful.

15 For two consecutive temperatures over 106°

a Remove blankets at once.

b Aspirin gr xv, and icecap to head stat.

c Glass of tepid water stat.

d Notify doctor stat.

e Prepare tub bath of 100°.

16 For temperature over 107° or too rapid rise in temperature

a. Remove blankets

b Give fluids freely

c Icecap to head, notify doctor stat.

d Aspirin gr xx-xxv p o, or sodium salicylate gr xxv-xl by rectum (in starch enema), or if child is unable to swallow or cannot retain an enema, antipyrine gr ii-x subcutaneously (Antipyrine is the only antipyretic sufficiently soluble to use by hypodermic.)

e Tub bath at 100°, cooled slowly to 80° while massaging.

f Cool colonic irrigation.

g Needle spray or cold pack with vigorous massage.

These routine orders for the treatment of hyperpyrexia may be omitted only if the person directing the treatment is on the floor and orders their omission. He may judge it wise to so order if the temperature appears to have reached a plateau level from which it will shortly descend.

Temperatures over 107° are uncommon and they have been invariably amenable to the treatment outlined above.

D—Duration of treatment The treatment should be given daily and stopped only when all the signs of chorea have dis-

CHART I

appeared except for the commonly found residual hypotonia. If seven or eight consecutive treatments do not effect a cure, the child should be given a rest for two to four days before resuming treatment. On the first day of the second

series of treatments, after a two to four day interval of rest, the same dose should be used as that of the last day of the first series.

E—Care during convalescence The child generally loses one to four pounds

CHART II

during the treatment period. Although the children stand this rather heroic therapy well and look surprisingly little worn out by it, it is customary to keep them in bed at least one week after the last treatment. If the sedimentation rate is elevated, or if there is any evidence of carditis, bed rest should be prolonged.

Patients are given a nourishing high caloric and high vitamin diet, and occupational therapy in the form of jigsaw games, weaving, and similar diversions. A two weeks sojourn in the country thereafter is very desirable.

F—General. The treatment should not be undertaken unless it is possible for all of the nursing orders to be carried out in a meticulous fashion. It must be borne in mind that it is possible for a temperature to rise four or five degrees in the fifteen minutes following a chill, and that one encounters, although rarely, children who will arrive at 106° in so short a time as three-quarters of an hour after the injection of the vaccine. The apparent fussiness in the technic detailed here is absolutely necessary to safeguard the patient. We feel, furthermore, that no one should attempt this therapy without having carried through at least six complete courses of treatment under supervision.

The course of a typical case of violent chorea is seen in Charts I-II. The improvement was rapid and complete. There were no discernible symptoms after twelve days of treatment and two days rest. It will be noticed that the temperature attained each day was very

close to 105°. Dosage was increased daily as it usually must be in order to reach the proper temperatures.

Results

Age and Sex. The females outnumbered the males by 23 to 1, the usual finding. The average age was nine years and eight months. The youngest child in the series was four years old and the oldest sixteen years.

Temperatures. Of the 433 treatments eighty-six per cent reached at least 104°, of the total treatments fifty-nine per cent were greater than 105°, twenty-two per cent greater than 106°, and six per cent greater than 107°. Capper and Bauer²⁶ state that the temperatures they achieved averaged only 102°-104°. They gave 297 injections to twenty-three patients, an average of thirteen injections per patient. We feel that the higher temperatures are more effective since our cases only required an average of 8.6 treatments per patient.

Analysis of results. A gross statistical analysis is presented in Table I. The average duration of symptoms from the inception of treatment was 12.2 days for the moderate group, 13.8 days for the severe group, and 22.5 days for the violent group. The average duration of symptoms for all groups was 14.3 days. This was longer than the average for the cases of Sutton and Dodge. However, their series included a much larger percentage of mild cases than did ours. They gave vaccine treatment to a large group of mild choreas. Such cases only re-

Without clinical rheumatism	24	16.6	31	9
With normal sedimentation rate	12	15	27.3	8.5
With elevated sedimentation rate	15	18.4	43	9

quired a few treatments, so that their average number of treatments and average days duration of symptoms were less than ours

The number of treatments required, for the different degrees of severity of chorea which we treated, was surprisingly constant being eight and nine for the three grades of chorea and 86 treatments for the total average

The average length of hospitalization was twenty-six days for the moderate group, for the severe group the average was 28.4 days, and the average for the violent group was forty-two days. The average length of hospitalization for the entire series was twenty-nine days. However, this average included the children who were found to have an elevated sedimentation rate

Sedimentation rates (Westgren method) were done upon admission on our last twenty-six cases (Table II). The average rate was twenty-two mm/hr. Of these cases, thirteen had rates under fifteen mm/hr, and averaged six mm/hr. The thirteen cases with rates greater than fifteen mm/hr averaged thirty-seven mm/hr

Of the fifteen cases which had sedimentation rates estimated all throughout treatment, thirteen rose following treatment. The average net increase in rate was twenty-six mm/hr. They generally fell to normal again within seven to thirty days. Two of the fifteen fell during treatment. These two had started with rates of 127 mm/hr and twenty-seven mm/hr respectively. None of these cases with elevated sedimentation rates had demonstrable foci of infection

The vaccine treatment apparently induces an elevation in the sedimentation rate. Whether this represents rheumatic activity or simply some physicochemical shift in surface tension, cell charges, or the like, is a problem warranting further research. It probably does not indicate rheumatic activity

Those children who had an elevated sedimentation rate after their course of treatment were kept in bed until the sedimentation rate became approximately normal. The figure for that group, forty-three days hospitalization, swelled the figure for the whole series to twenty-nine days average hospitalization. Neverthe-

less, twenty-nine days is a comparatively short hospital period for chorea. If the high sedimentation rates had not influenced our management of convalescence, the hospital period for the fifty cases would average about twenty-one days

It is of interest that the children with clinical rheumatic fever (enlarged heart, apical systolic murmur, or arthritis) have the smallest average figures of any group in Table III. This may be due to statistical error consequent upon inadequate numbers

In the twenty-two cases with clinical rheumatism, the average duration of chorea was 11.7 days, the hospitalization period twenty-six days, and the number of treatments eight. The twenty-four cases without clinical rheumatism averaged 16.6 days duration of symptoms, thirty-one days hospitalization, and nine treatments. The twelve children with normal sedimentation rates had symptoms for fifteen days, were hospitalized an average of 27.3 days, and had an average of 8.5 treatments. Those with an elevated sedimentation rate, fifteen cases, had their symptoms last for 18.4 days, their hospitalization averaged forty-three days, and they required an average of nine treatments

In such a small series, fine division of the figures into so many categories can be only suggestive at best. It seems, however, that the cases with an elevated sedimentation rate had a longer duration of symptoms than cases which came under any of the other classifications in Table III

Asche and Einhorn,¹⁰ in a recent publication, voice the fear that protein shock may activate a dormant rheumatic fever. Of their seventeen cases of chorea to whom typhoid paratyphoid vaccine was given intravenously, three showed increasing carditis during treatment, one case terminating fatally six weeks after the last injection. They quote Jones¹¹ who reported that of twelve patients who were given typhoid vaccine therapy during their convalescences from acute rheumatic fever, six cases developed exacerbations of their rheumatic fever in from twenty-four hours to three weeks

It appears to us that these episodes may have been relapses rather than recrudescences. It is not uncommon to en-

TABLE IV—Incidence of Rheumatic History, Heart Lesions, and Sequellae

counter occasional flare-ups during the convalescence of rheumatic carditis. Table IV shows that only three cases (12%) of our choreas without rheumatic history or clinical rheumatism on admission subsequently developed permanent apical systolic murmurs. In evaluating the appearance of a systolic murmur at the apex in these three cases subsequent to vaccine therapy, it should be borne in mind that a not inconsiderable percentage of choreic children develop rheumatic heart disease during or following their chorea, even when treated with rest and sedatives alone. We believe an incidence of twelve per cent is rather small.

This table also shows that of the twenty cases with mitral insufficiency on admission only one went on to an exacerbation of his existing carditis following treatment. The exacerbation took place fourteen months after discharge. One of these cases had a mild attack of arthritis two months later.

On the other hand, three cases (15%) of this cardiac group were found to have entirely negative hearts shortly after treatment and their hearts remained so on follow-up. We did occasionally find a transient apical systolic murmur without enlargement during or immediately after treatment. This disappeared within a few days. On clinical grounds we do not share the concern of Asche and Einhorn, in which we are supported by the recent opinion of Sutton and Dodge.

It will be noticed in this table that five children were admitted with the history of joint pains, and six admitted with the history of frequent tonsillitis.

Effectiveness of treatment. Upon discharge forty-six of our cases, or ninety-two per cent, were completely symptom free. Two children were only somewhat improved but were among our early cases and should perhaps have been more vigorously treated. Only two children failed completely to benefit from the treatment. These two subsequently developed the mask-like facies and diminution of associated movements characteristic of the postencephalitic syndrome. We have tried vaccine therapy upon known postencephalitics to no avail. However, an occasional failure is to be expected, the percentage of refractory children is very small.

Recurrences. Five of our cases (10%) have had a total of six recurrences in the one-three year follow-up period to date.

The clinical estimations of the duration of choreic symptoms, when treated with miscellaneous remedies, are classified in Table V. Many of the observers did not report the number of cases they had seen. However, from the figures available, there are well over 1300 cases reported. It will be seen that the average duration of symptoms, for all observers, is 60.5 days. No complications were reported. Our series of seventy-five cases is included. Our cases were those treated on this service prior to 1930. They were well distributed into the three groups of mild, moderate, and severe. The remedies used for our cases and for the cases of the other observers listed in Table V were manifold. They included simple bed rest, sedatives, baths, warm packs, cool packs, salicylates, thyroid extract, massage, electrotherapy, Small's serum, intraspinal autoserum, and many medications, chief of which was Fowler's solution. In addition, various diets were used, among them being the high carbohydrate, the ketogenic, and the starvation diets. We feel that this group of over 1300 cases may be taken as a control group, and that 60.5 days may be considered a rough estimate of the duration of untreated or symptomatically treated chorea.

Nirvanol (phenyl-ethyl-hydantoin) was introduced in 1919 for the treatment of chorea by Roeder.¹⁸ It has since been subjected to a wide clinical trial, principally in Germany, England, and the United States. There has been considerable disagreement about its values and its dangers. Unfortunately the available articles contain somewhat incomplete statistical analyses, thus making comparison with other methods difficult. In the total series of 178 cases, there were two deaths and one severe pneumonia reported (Table VI). One hundred and thirty-seven cases (77%) were reported cured, twelve (6%) improved, and twenty-nine (17%) unimproved. The duration of symptoms for all the observers quoted averaged 25.4 days per case. It is evident that severe complications and fatalities have been noted.

It is a matter of interest that at least

sixty per cent of the children treated with nirvanol run a temperature of 102°-104° for a few days. The hypothesis that this hyperpyrexia is to some extent responsible for the beneficial effects of nirvanol is not entirely unlikely.

Nirvanol is a proprietary drug imported from Germany. The different lots received often seem to vary greatly in toxicity and it is necessary to do white and differential blood counts at least as often as every other day. The effect of the drug is cumulative and nirvanol poisoning is the end point desired. This end point seems perilously close to agranulocytosis. The variable potency of the drug, the frequent blood counts, the longer duration of symptoms, and the longer hospital stay, are factors to be considered when comparing this method of treatment to the vaccine method. The vaccine method requires only two blood counts, one before and one after the series of injections, the vaccine is inexpensive, readily available, and well-standardized, and the hospital stay is comparatively short. The complications and fatalities reach a significant number

with the nirvanol treatment, the vaccine treatment seems free of such.

The calcium-aspirin therapy recommended by Mutch²⁵ does not seem to offer much promise. Mutch reports that his seventeen cases all had "their symptoms arrested" however, the term "arrested" is not defined. We gave calcium-gluconate intramuscularly (10 c.c. twice a day for five days) to five mild choreas with no demonstrable benefit.

Table VII contains an analysis of all the larger series of choreas treated with intravenous typhoid paratyphoid vaccine including our own. Of the total 270 cases, 246 (92%) were cured, six (2%) improved and eighteen (6%) unimproved. The average duration of symptoms, from inception of treatment, was 11.9 days. There were no noteworthy complications attributable to the treatment.

Table VIII compares the grouped results of the reports on nirvanol with the grouped result of the reports on typhoid paratyphoid vaccine. Of the 178 cases treated with nirvanol, seventy-seven per cent were cured, of the 270 cases treated with typhoid paratyphoid vaccine, ninety-

Average number of treatments all cases — 8.6.

two per cent were cured. There were six per cent improved with nirvanol, and two per cent with vaccine, there were seventeen per cent unimproved with nirvanol, and only six per cent unimproved with vaccine. The duration of symptoms with nirvanol averaged 25.4 days while the duration of symptoms averaged only 11.9 days with the vaccine. Two deaths and one pneumonia were reported following the use of nirvanol therapy, there were no noteworthy complications with vaccine.

Discussion

Sydenham's chorea is ordinarily a self-limited disease. A majority of the children recover from their symptoms in approximately eight-ten weeks. Why then should so much concern be manifested in this syndrome and so much endeavor be directed towards remedial measures? There are several reasons. A choreic child is an unpleasant sight to others and to himself, and is very unhappy, he is a vulnerable subject for psychic trauma. It is common knowledge that a relatively high percentage of these children become introverted, neurotic, and even psychotic adults.

It might be argued that since chorea is ordinarily self-limited, many of our cases were about to undergo spontaneous remission at the time when vaccine therapy was initiated. For the moderate cases with a duration of less than twenty-one days of symptoms before admission an average of seven treatments were necessary, the moderate cases with a history of symptoms for twenty-two to forty-two days previous to admission required an average of 7.2 treatments, and where the symptoms had been noticed in the moderate group for more than forty-two days prior to admission, 13.5 treatments (Table IX).

The severe group required 8.4, 9.5, and eight treatments respectively for the three different classifications of duration of symptoms prior to admission. The violent group were all brought to us in less than twenty-one days after the onset of symptoms. Our fifty cases had an average history of a forty day duration of symptoms before admission.

Of all cases, nineteen had had symptoms for less than twenty-one days and required an average of eight treatments, seventeen had had symptoms for from twenty-two to forty-two days and required an average of nine treatments and ten had had symptoms for more than forty-two days before coming to the hospital and needed an average of nine treatments. The average number of treatments for all cases was 8.6. These figures show, therefore, that it was fully as difficult to cure those children with a very long history of chorea as it was to cure those whose history only dated back to twenty-one days or less. There are

four cases classified in the last column whose chorea had been evident for more than six months.

For many years there has been considerable interest centered on the question of the relationship of chorea to rheumatic fever, and especially rheumatic carditis. The coincidence of chorea and carditis has been estimated to be as low as twelve per cent and as high as seventy-two per cent (Table IV). Forty per cent of our cases had enlarged hearts with apical systolic murmurs on admission. As mentioned before, only three of our cases or twelve per cent were found to have acquired rheumatic heart disease subsequent to treatment, and only one case, of the group admitted with rheumatic heart disease, later went on to an exacerbation, while three of the group admitted with rheumatic heart disease were found to have negative hearts following treatment. We have had to date a total of but six choreic recurrences in five children in the one to three year follow-up period.

So it may be possible that by aborting chorea we are reducing the duration of the rheumatic infection and the possibility of more serious rheumatic episodes, as well as benefiting existing rheumatic heart disease, as claimed by Sutton and Dodge.

It seems justifiable to us to treat these children with this admittedly drastic treatment until a more ideal method is found.

It is comparatively inexpensive, safe if competently supervised, and promises a short hospital stay. It offers a high percentage of cures, and what effect it has upon active carditis seems to be beneficial. If chorea is to be treated, in a hospital, by measures other than simple bed rest and sedatives, we feel that the vaccine treatment is at present the treatment of choice.

Conclusions

1. Fifty cases of severe chorea were treated with intravenous typhoid paratyphoid vaccine.

2. Ninety-two per cent were cured. There were no ill effects.

3. Ten per cent had a total of six recurrences one-three years following treatment.

4 The treatment compares favorably with the nirvanol treatment and other measures

5 Active carditis does not seem to be a contraindication to this treatment

6 Meticulous care in dosage and nursing is essential, the method is safe in experienced hands

7 It appears to be the hospital method of choice at present

Acknowledgment is made to Dr Adolph G DeSanctis, Director of the Pediatrics Department, New York Post-Graduate Medical School and Hospital, for his kindness in authorizing this work.

Acknowledgment is also made to the Nursing staff for their efficient cooperation.

We appreciate the constructive advice and criticism of Dr Lucy Porter Sutton and Dr Katheryn G Dodge.

Discussion

DR PAUL W BEAVEN, *Rochester, N Y*—In the last few years artificial fever has been used therapeutically in a number of diseases, notably pneumonia, paresis, arthritis, chorea, and gonorrhea. The chief method of producing fever has been by inoculating intravenously typhoid paratyphoid vaccine. Malaria has been given to paretic cases simply for the fever it induces, and the so-called "fever cabinet" has also been used to create higher temperatures.

Dr Weisman's paper is a very careful analysis of a method of therapeusis for chorea, and one in which we are all interested. Choreia is a self-limited disease, and when it is mild, I feel as Dr Weisman does, that only simple measures are indicated. Children who have the disease severely need any treatment that is at the same time relatively harmless and effective in calming their symptoms.

At the General hospital we have used typhoid paratyphoid vaccine on a number of chorea cases, and in some the results have been amazingly good. We have had children, as did Dr Weisman, ask for more treatments. In others, however, we did not get what we considered adequate benefit. Perhaps we did not use enough of the vaccine. Dr Weisman does not give us the amount that he used. We tried to raise the fever to approximately 104° and 105°. Dr

Weisman, however, almost routinely produced 105, and occasionally 107°, and he gave it oftener and longer than we did. Our general routine was to give a treatment every three days. Our feeling was that if after three or four injections, there was no benefit, there would be none. At the Strong hospital two cases have been treated by the "fever cabinet," one of which was very much helped, but the other was not helped at all. The problem which naturally rises in this form of treatment is how long should the fever be given. More cases will have to be treated to determine the optimum time for this treatment, and to discover its contraindications and its value. I understand that such a study is being conducted at Bellevue hospital by Smith, Sutton, and Dodge.

Asche and Einhorn in Philadelphia have called attention to danger in the use of typhoid vaccine in cases of chorea which are complicated by carditis. Dr Weisman does not think carditis is a contraindication unless it is associated with signs of decompensation. Our experience would coincide with Dr Weisman's.

One modification in the technic of giving vaccine has been introduced by Dr Weisman, and I feel it is a valuable one. He quiets these children with sodium amylal before they were given their inocula-

tions I quite agree that the sodium amytal in itself would have no real beneficial effect on the length or severity of the choric symptoms

Personally, I do not share the apprehension Dr Weisman possesses concerning the use of nirvanol, as this drug has been my method of choice in these cases. Dr Weisman raises the objection to nirvanol that there have been two deaths from this drug. However, it is not at all clear that these two cases were affected by the administration of nirvanol itself. He also states that this drug has variability in its potency. It is true that it acts differently on different children, but this may not be inherent to the drug. Nirvanol possesses the advantage

which often is a distinct one of keeping these youngsters at home when sending them to the hospital is impossible or inadvisable. I think our experience in Rochester would be that the length of duration of symptoms after the treatment of nirvanol is approximately the same as the treatment with typhoid vaccine. It certainly is a much simpler method.

I think Dr Weisman's results are better than we have had in Rochester, although we have not had as many cases, and our methods varied slightly. The value of this treatment can only be determined, however, by just such analyses as Dr Weisman has presented.

SCOTCHING A CRUEL \$1,000,000 SWINDLE

Postal sleuths in Washington announce break-up of a nationwide "glimmer racket," through which some of the cruelest criminals on record have swindled the aged and the ailing of more than \$1,000,000.

Chief K. P. Aldrich, dean of Federal law enforcement officials, said his men had arrested seventeen of the public enemies, who have sold thousands of cheap glasses for \$100 or more a pair, who have performed fake eye operations in the living rooms of their victims, and who otherwise have preyed on the ills of elderly farmers and their wives.

"The swindlers specialize on those who are 70 or over," the postal inspectors said. "The ease with which they extort large sums of money from their victims is surpassed only by the brutality of their scheme."

The agents described the operation of the racket thus:

"Finger men" travel about the country selling eye glasses for all the traffic will bear. One ninety-eight-year-old man was induced to pay \$100 for glasses worth \$3.75. A few weeks later the same impostor sold him another "stronger" pair for \$135.

The "finger men" furnish the names of their victims to other members of the gang, known as "specialists," for a twenty per cent commission on profits yet to come.

The "specialists" usually pose as celebrated physicians and frequently bring their women "nurses" with them into the rural communities where the racket is worked exclusively.

The pseudo-physician examines the eyes of his credulous client, is aghast at the type of glasses sold previously by his confederate, and says that an operation is necessary immediately, if his victim is to live more than a few days.

The postal inspectors said this is the way the "operation" is performed.

"The fake doctor has his patient lean back. The head is dropped farther backward. An eye-dropper is inserted into a green opaque bottle, heavily corked, and a very few drops of the precious liquid, represented to be radium but actually some patent eye preparation, are withdrawn. After these drops are put into the eye, a blunt pair of medicated cotton-tipped medical tweezers are used to rub the medicine around in the eyes as an occasional drop is added."

Then, through some hokus pokus of the vaudeville magician, the "specialist" apparently withdraws from the eye a "malignant growth" which in reality is a piece of rubber brought along for that purpose. He immediately destroys it. Then he places a good pair of eyeglasses on his victim, whose sight immediately improves. This sort of operation, the agents said, frequently has cost an unwary citizen \$800 or \$900.

Usually after one of these "operations" on a victim who still has money left in the bank other impressive-looking members of the gang visit him about two weeks later and "lend" him a radium belt, which they guarantee to make him feel young again.

The belt is so valuable, they say, that they must have a deposit of \$1,500 to insure its safe return. One woman in Massachusetts even paid a \$2,000 deposit. She still has the belt, the criminals have her money, and she feels same as ever.

Of the seventeen men arrested—several in the last few days—two have been convicted, while the rest are being held for trial. Other members of the medical gang still are being sought.

4 The treatment compares favorably with the nirvanol treatment and other measures

5 Active carditis does not seem to be a contraindication to this treatment

6 Meticulous care in dosage and nursing is essential, the method is safe in experienced hands

7 It appears to be the hospital method of choice at present

Acknowledgment is made to Dr Adolph G DeSanctis, Director of the Pediatrics Department, New York Post-Graduate Medical School and Hospital, for his kindness in authorizing this work.

Acknowledgment is also made to the Nursing staff for their efficient cooperation.

We appreciate the constructive advice and criticism of Dr Lucy Porter Sutton and Dr Kathryn G Dodge.

Discussion

DR PAUL W. BEAVEN, *Rochester, N. Y.*—In the last few years artificial fever has been used therapeutically in a number of diseases, notably pneumonia, paresis, arthritis, chorea, and gonorrhea. The chief method of producing fever has been by inoculating intravenously typhoid paratyphoid vaccine. Malaria has been given to parietic cases simply for the fever it induces, and the so-called "fever cabinet" has also been used to create higher temperatures.

Dr Weisman's paper is a very careful analysis of a method of therapeutics for chorea, and one in which we are all interested. Choreia is a self-limited disease, and when it is mild, I feel as Dr Weisman does, that only simple measures are indicated. Children who have the disease severely need any treatment that is at the same time relatively harmless and effective in calming their symptoms.

At the General hospital we have used typhoid paratyphoid vaccine on a number of chorea cases, and in some the results have been amazingly good. We have had children, as did Dr Weisman, ask for more treatments. In others, however, we did not get what we considered adequate benefit. Perhaps we did not use enough of the vaccine. Dr Weisman does not give us the amount that he used. We tried to raise the fever to approximately 104° and 105° Dr

Weisman, however, almost routinely produced 105°, and occasionally 107°, and he gave it oftener and longer than we did. Our general routine was to give a treatment every three days. Our feeling was that if after three or four injections, there was no benefit, there would be none. At the Strong hospital two cases have been treated by the "fever cabinet," one of which was very much helped, but the other was not helped at all. The problem which naturally rises in this form of treatment is how long should the fever be given. More cases will have to be treated to determine the optimum time for this treatment, and to discover its contraindications and its value. I understand that such a study is being conducted at Bellevue hospital by Smith, Sutton, and Dodge.

Asche and Einhorn in Philadelphia have called attention to danger in the use of typhoid vaccine in cases of chorea which are complicated by carditis. Dr Weisman does not think carditis is a contraindication unless it is associated with signs of decompensation. Our experience would coincide with Dr Weisman's.

One modification in the technic of giving vaccine has been introduced by Dr Weisman, and I feel it is a valuable one. He quiets these children with sodium amytal before they were given their inocula-

six per cent of the total calories whereas fat contributes from thirty-three to thirty-nine per cent of the total calories. The caloric contribution of protein is remarkably constant at approximately eleven per cent of the total calories used. This in a general way is in accord with the observation of Rubner, Voit, Lusk, Greenwald,⁹ and many others. Cathcart also reproduces a summary of Greenwald showing the percentage distribution of calories in the dietaries of fifteen widely scattered nations (Table I).

TABLE I.—PERCENTAGE DISTRIBUTION OF CALORIES

	No of studies	Protein	Fat	Carbo
Britain	25	12.5	25.5	62.0
Belgium	7	11.7	30.2	51.1
Denmark	6	12.3	27.8	59.9
Finland	8	16.4	29.1	54.5
France	1	15.5	12.9	71.6
Germany (less exper diets)	9	14.1	18.4	67.5
Greenland	1	44.0	48.0	8.0
India (native only)	4	9.6	21.8	68.6
Italy	11	14.8	13.1	72.1
Java (Malaya)	1	8.9	8.3	82.8
Japan	14	12.1	5.9	82.0
Russia (less Volga fishers)	13	15.8	16.1	68.1
Sweden	8	12.3	38.1	49.6
Switzerland	1	13.8	27.2	59.0
United States	27	12.3	34.2	53.5

It will be noted that with the exception of Greenland and Sweden all other nations derive less than thirty-five per cent of their calories from fat. Assuming that the basal caloric requirements of the "normal diet" described by Hill are as stated and that the man engaged in pursuits which involve an average further caloric expenditure, the increase over and above the basal requirements amounts to approximately one hundred per cent, i.e., 3100 or 3200 calories.

Wilder¹⁰ in a recent review makes the statement that the caloric requirements for his diabetic patients are calculated as being the basal requirements plus fifty per cent. This was not an uncommon standard used in calculating caloric requirements in the pre-insulin era. The total calories in the type of diet which Wilder prescribes for the adult male diabetic patient would therefore amount to approximately 2400 calories, conceding that the average man referred to above in the Royal Society Report has a basal requirement of 1600 calories. Again, if this diabetic patient were engaged in occupation similar to the variety of oc-

cupations studied by Cathcart, he would necessarily become an undernourished individual. Although the recent brilliant work of Houssay¹¹ demonstrating the inhibiting effect of the pituitary upon insulin effectiveness, the work of Long and Lukins,¹² which has further confirmed the importance of the influence of the adrenals on glycosuria, and the effect of thyroid on sugar metabolism are well-known, nevertheless, there is no disorder of any or all of these endocrine glands, as far as it has ever been demonstrated, which produces true diabetes mellitus. It is true that various disorders of one or all of these glands exert their influence upon the course of the disease. Most of these influences tend to offset the activity of insulin. Diabetes, as has been conclusively demonstrated, is primarily and essentially a disorder of metabolism due to insulin insufficiency. This insufficiency, of course, varies considerably with the degree of severity of the diabetes, and in the later stages in the juvenile types of this disease, insulin must be minimal if not entirely absent. If we assume that the normal individual secretes approximately one hundred units of insulin per day and that a given case of diabetes secretes only fifty units per day as a yearly average, then the difference between this deficiency and the normal will amount to fifty units. If this amount of insulin, properly distributed over the twenty-four hour period to prevent glycosuria, is administered parenterally, the total amount of insulin available to this diabetic will be one hundred units, which is equal to the pancreatic yield of the normal man. Is it therefore not reasonable to assume that this patient will be able to properly metabolize a normal diet? We have assumed that such is the case and that such a diet should be normal not only as regards its total caloric content but also as regards the proportion of grams carbohydrate to protein and fat. That this hypothesis has been proven correct is attested to by our own experience in treating diabetic patients during the past eleven years and has been amply confirmed by other investigators.

Objections to this type of therapeutic procedure have been many. First, that the desideratum of treatment is to feed an "adequate diet" and to control gly-

Symposium: Endocrine Glands

PROBLEM OF THERAPEUSIS IN DIABETES

H RAWLE GEYELIN, M D, *New York City*

In previous communications¹ we have demonstrated the benefits derived from feeding diets, normal in their caloric values and in the proportions of carbohydrate, protein, and fat to insulin treated cases of diabetes. In spite of the fact that the advantages of these diets as compared to other less normal diets employed in the treatment of diabetes have been confirmed by numerous observers both in this country and abroad, there remains a group of prominent clinicians who prescribe various modifications of the older pre-insulin types of diet. It is the purpose of this paper to present additional evidence of the advantages derived from the new as compared to the old pre-insulin types of treatment. The fundamental characteristics of most of the diets just alluded to as the "old diets" are (1) the preponderance of calories derived from fat, i.e., more than fifty per cent of the total and (2) the fact that the total calories fed are below those of the normal diet for a patient of given weight, age, sex, and occupation.

It is, I believe, generally accepted that in this country and Western Europe the diet of the average normal adult or child has a relationship in grams carbohydrate, protein, and fat of approximately 4-1-1 respectively. This proportion of essential food materials is agreed to by Rubner,² Voit,³ Joslin,⁴ Lusk, Cathcart,⁶ and many other observers. The first two mentioned authors find that normal adults eat a diet which is even higher in its ratio of carbohydrate to fat. While it is true that not all of the objectors to the so-called normal or high carbohydrate diet prescribe diets which are sub-normal in total calories, nevertheless the proportion of fat prescribed even in the normal caloric diets is of necessity proportionately higher than normal in order to bring the total calories up to the standard requirements of normal people (See Table IV).

Before proceeding to a further discus-

sion of the dietary therapeusis in diabetes, it is necessary to present the opinions of various authorities who have investigated the problem of what the normal man eats, not only as regards the proportion of carbohydrate, protein, and fat but also the total calories. Hill,⁷ referring to the food requirements of a normal individual, says

According to the Royal Society report, the "average man" should be defined as an adult man of sixty-six kilos (145½ pounds) performing eight hours average work in a climate such as that of France or England—should be between twenty-five and fifty years of age—171 centimeters in height (5' 7¼"). The basal requirements of such a man have been found by experiment to be 1687 calories. Harris and Benedict found that the average basal metabolism of normal men is measured by a daily heat production of about 1600 to 1650 calories.

Voit came to the conclusion from the study of a very limited number of subjects that diet yielding just over 3000 calories sufficed for the man performing work more strenuous than a tailor's but not so exhausting as a blacksmith's.

Atwater has put the value for an average man's diet somewhat higher, between 3300 and 3500 calories per day. Contributors to this work such as Rubner, Lusk, Murlin,⁸ and others put the caloric needs for the average worker as 3100 calories plus or minus 400 calories depending upon the sex, age, activity, and climate. Cathcart, in an admirable and detailed study of food intake of 154 families in St. Andrews, Scotland, finds that the average diet of all male groups studied other than the unemployed consumed from 3333 calories to 3020 calories. The mean value for the 154 families (745 individuals) was $411-84-119 = 3119$ calories. The absolute number of grams of carbohydrate fed varies from 407 to 421 grams per day while the fat varies from 107 to 140 grams per day. Carbohydrate therefore constitutes from fifty to fifty-

"customary diet" with approximately twenty to thirty per cent less calories derived from fat. Example Assuming that the patient is overweight on a diet which approximates 400-90-130, without reducing the amount of carbohydrate and protein, the fat is reduced by at least twenty to thirty per cent, and the dosage of insulin so regulated as to frequency, timing, and amount that any glycosuria resulting from such a diet is controlled.

Fourth, patients who are neither overweight or underweight on their "customary diets" before the discovery of diabetes are allowed to remain on these diets. The directions regarding insulin are the same as for Group 3.

Fifth, in the case of undernourished patients, particularly those in the juvenile group of diabetes, the normal or "customary diet" is increased calorically five to ten per cent.

In refutation of the statement that the administration of normal carbohydrate diets increase the demand for insulin, we cite the following case

CASE 1 F T, female. Her diabetes was first discovered August 1929 at the age of five. During the first few months, as will be noted in Table II, the diet was low in carbohydrate and total calories. The dose of insulin given (20 units) failed to control glycosuria entirely, and she was also having rather severe insulin reactions. The parents were not satisfied with her progress and rightfully so. She was taken to another physician where the diet was increased to 1684 calories. Both the carbohydrate and the fat of this diet were relatively low. When first seen in 1932, three years after the onset of diabetes, she was extremely thin, weak, fretful, hungry, and stealing food. She was at that time still showing considerable amount of sugar in her urine, often as high as six per cent, interspersed with this high degree of glycosuria were rather frequent and severe hypoglycemic reactions. The marked glycosuria had necessitated an increase of insulin from forty-two to eighty units per day. From December 1932 until April 1936 this child gained nearly thirty pounds in weight and eight inches in height. She is now of normal size (not over-size), is not hungry, and requires less insulin on a diet of 308-83-84 than she did when she was having a diet of 149-74-88. The average daily amount of glycosuria which obtained over a period of three months prior to her first visit was between thirty to fifty grams a day. During the first year of treatment this glycosuria persisted in slightly diminished

amounts. During the past two years or more the glycosuria rarely exceeds ten grams per day, and there are many days when the urine is sugar free. Because of the suddenness, the extreme severity and long duration of this child's insulin reaction, the parents cannot be persuaded to maintain the urine completely sugar free. It should also be noted in this patient that there were many areas of fat atrophy over

TABLE II

	At onset Aug. 1929	Previous to first visit	First visit 12-17-32	Last visit Apr. 1936

the thighs and buttocks when she was first seen. These have recently completely disappeared. The features to be emphasized in this patient are (1) Potential dwarfism due to undernutrition has been overcome, (2) No more insulin is required to maintain the same level of freedom of sugar in the urine than was required on the lower carbohydrate and lowered caloric diet.

CASE 2 S R, male. His diabetes was first discovered August 1931 at the age of

cosuria with the least possible amount of insulin. This, it is said, can not be done when high carbohydrate is fed because it increases the amount of insulin required.¹⁸ These critics of the normal diet make the assertion that only a comparatively small number of diabetics can be successfully treated with the higher carbohydrate diets without involving a great increase in the amount of insulin administered. This has not been our experience. The large majority of diabetics on a normal diet require no more, little more or even less insulin than does the same patient on a high fat diet equal in calories. Those who have employed the normal diet in the treatment of their insulin cases confirm this statement. As far as I know, none of the clinicians who object to the use of the normal diet have ever employed it over long periods in the treatment of any considerable group of cases.

A second objection has been that a diabetic patient who is allowed a large amount of carbohydrates loses his power of self-discipline with regard to food, with the inference that those treated with lower carbohydrate diets achieve and maintain self-discipline. How fallacious this inference is, is attested to by the fact that the last fourteen patients who have come under my care after having several years of treatment with low carbohydrate high fat diets (that is to say, these were the diets prescribed) have been overeating their diets consistently and have made very little pretense of adhering to the diet prescribed except at the time they pay semi-annual or annual visits to their physicians.

A third objection has been that the patients treated with normal diet show a greater amount of glycosuria than do cases treated with lower carbohydrate diets. While it is true that approximately ten to fifteen per cent of the cases which are under my supervision show a moderate but fairly persistent glycosuria—usually not more than five to ten grams daily—it has been my observation that an equal number of diabetic patients show glycosuria in equal amounts under any system of treatment, particularly a system that compels the breaking of diet.

The purpose of the present communication is to present further evidence and

amplify some of the past material presented in confirmation of the statement that diabetes under insulin treatment is more adequately controlled by the administration of normal diets than with diets either below normal in calories or abnormal in their proportion of carbohydrate, protein, and fat. There is ample evidence, both experimental and clinical, that excessive fat tends to lower the tolerance for glucose⁴ and for this reason we have lowered the fat intake in some cases below the level which might be considered normal for most people. Wilder,¹¹ in reviewing the most recent edition of Joslin's book, "The Treatment of Diabetic Mellitus," quotes Dr. Joslin on the subject of diabetic dwarfism as follows: "This condition today is probably inexcusable." In our opinion this statement should be revised to read: since the discovery of insulin this condition has always been inexcusable. It is difficult to understand the point of view of the clinician who is satisfied with the treatment of diabetic children over a period of years with diets which are in many instances far below the carbohydrate and caloric requirements of normal children and whose growth and general development are minimal or stationary over periods of years (See Table II). Many of such patients coming from other physicians have either been pathetic martyrs to hunger or else they have been stealing food. Unfortunately, most of them have not been stealing enough food and have therefore remained stunted or undernourished. As a matter of fact, the majority of insulin treated cases of diabetes, be they children or adults, unless they are allowed to eat normally, take the matter of diet into their own hands, particularly those who are suffering from under-nutrition.

The following technic for the management of all insulin treated cases of diabetes has been developed.

First, we determine whether the patient is overweight.

Second, we ascertain as nearly as possible what the customary pre-diabetic diet of that individual has been in terms of grams carbohydrate, protein, and fat. This is accomplished either at home or in the office with the help of a skilled dietitian.

Third, if the patient is found to be overweight, the diet prescribed is the previous

was considerable daily glycosuria. The need for insulin steadily increased until in March 1931, she was requiring an average of seventy-seven units per day. Since that time, and particularly since the time of the last report, (1934) the insulin requirements have diminished to fifty-two units a day with almost complete freedom from sugar. She attributes this to the lower amount of fat that she is eating (Table VI.)

CASE 6 T H, male, age at onset eleven years, seven months. This patient illustrates the prolonged effects of undernutrition. For four years the total caloric intake had not been raised above 1910 calories. His mother thinks, but is not sure, that a few months after the onset he received as high as 2500 calories. This is doubtful, at any rate, for the major portion of four years the diet was as indicated in Table VII and he gained only seven pounds in weight and less than an inch in height. His small stature is particularly noticeable when one notices the unusually large size of his feet and hands. Five brothers, one of whom has diabetes, are over six feet tall as is also the father. His mother is five feet, eleven inches. The patient, who was nearly sixteen years old when first seen, was less than five feet tall and weighed only 107 pounds. After increasing the diet and raising the carbohydrate, he has gained nearly three inches in height and nineteen pounds in weight in nine months. An interesting feature in this boy's case is that if he is given any insulin before supper, even if the dose is as low as two units, very severe convulsive hypoglycemic reactions occur in the early morning. At the present time he is receiving only twelve units in the morning before breakfast.

CASE 7 I H, male, age thirty-two. This patient after being under my care for several years for mild asthma came to me in April 1930, complaining of daily attacks of weakness, sweating, tremor, and a hollow, hungry feeling. He had discovered that these attacks were instantly relieved by sugar. They always occurred at 4 P.M. at least four or five times per week and had begun two months prior to his coming to consult me. The blood sugar determination made at 11 A.M. was eighty-two milligrams per 100 c.c. of blood. Another determination obtained at 4.30 P.M. on a day when he did not have an insulin reaction was as low as sixty milligrams per 100 c.c. of blood. These attacks continued for another two or three months and then disappeared. There was never any sugar found in the urine. The average weight of this patient had been 178 pounds over a period of five years, but at the time of the onset of what may have

been hypoglycemic symptoms, his weight was 191 pounds.

The patient was not seen again until February 23, 1932 at which time he came in complaining that for the past two months he had been suffering from fatigue, weakness, loss of weight, and nocturia. There was no other evidence of diabetes but his urine showed five per cent sugar. The blood sugar was 233 mg per 100 c.c. and the blood cholesterol was 242 mg per 100 c.c. He was put on a diet of 250-85-80 and desugarized with twenty-five units of insulin. His weight at this time was 178 pounds. From February until December, he lost nine pounds in weight and claimed he was hungry. The diet was then increased to 400-95-80 insulin, twenty-eight units. In July 1933, the diet was again raised, 400-100-95. He was sugar-free on twenty-two units of insulin, but his weight had dropped to 162 pounds. In August, the weight had dropped to 160 pounds and then later to 156 so that the diet was raised to 430 grams carbohydrate, 125 grams of protein, and 105 grams of fat. He was at that time engaged in vigorous outdoor exercise, chopping wood, etc., and found that it was possible to lower his insulin to seven units per day. On one occasion he took only four units and yet the urine was free from sugar. The patient stated that he was sure he could have kept sugar free entirely but he was too apprehensive of a reappearance of glycosuria. His parents at this time were not convinced that he had diabetes and during the fall of 1933, he consulted Dr. Joslin. At that time his weight was 160 pounds. He was put on a diet of 250 grams carbohydrate, 125 grams of protein and 135 grams of fat. He was easily desugarized but was discharged from Dr. Joslin's clinic on November 28, 1933 on an insulin dosage of twenty-two units. The urine contained considerable amounts of sugar, i.e., 3.4 per cent on the day of his discharge with a blood sugar of .36 per cent.

For the following year he adhered strictly to the diet prescribed by Dr. Joslin and finally on October 1, 1934, he returned to my care requiring fifty-two units of insulin to keep him sugar-free. He was showing one per cent sugar in his urine in a twenty-four-hour specimen. Diet was then changed to 325-90-90 and on December 5, 1935 he was sugar-free had gained eight pounds in weight, and required forty-two units of insulin.

Summary

The cases presented are only illustrative chosen because they represent the usual course of events when diabetic

fifteen Shortly after the onset of his diabetes this patient was treated by Dr Carl Van Norden for more than a year The diet, insulin requirements, etc., may be seen in Table III The boy's parents were not satisfied with his progress and finally transferred him to the care of Dr Porges in Vienna It will be observed that the diet prescribed at that time, although approximately normal in carbohydrate was rela-

TABLE V

	At onset Jan. 1930	Previous to first visit	First visit 6-4-32	Last visit Sept. 1935

* Four plus sugar is not present every day and when present is only in forenoon urine, i.e. between 9 and 11 A.M. All other readings are sugar free

tively high in fat. At first it was necessary to give as much as 120 units of insulin but within two months it was possible to reduce the daily dose to seventy units, and the patient was sugar free twenty-five days out of every month in all specimens voided. After his first visit to me, it was necessary to increase the insulin as indicated in the table, but this increase was not needed for more than two months, and then the dose

was again lowered to seventy units per day as indicated. The diet prescribed by Dr Porges had been in effect for only six months when he was first seen by me, and he still gave the appearance of a thin, rather undernourished youth In the past year and three months, he has gained twelve pounds and presents the picture of normal nutrition Again, this patient illustrates the fact that no increase in insulin is necessary to maintain a sugar free urine when the diet was raised from 100 to 450 grams carbohydrate (Table III) There is also the added fact that a moderate degree of under-nutrition has been overcome

CASE 3 W I, male, age at onset twenty-one years, eight months The course of the diabetes as shown in Table IV is again illustrative of the decreased demand for insulin after transferring from a high-fat to a high-carbohydrate diet. This patient was included in a previous publication and is presented here merely to extend the period of observation He was last seen in February 1935 with the record as observed in the table He writes me that he is still sugar free ninety-five per cent of the time and is taking forty-six units of insulin This patient has always presented the appearance of leanness almost to the point of undernutrition It has been suggested to him that he can have more food, but he says that he doesn't want it except on days when he plays tennis Another interesting feature of this case is the reduction of the blood cholesterol that followed his transference to the high carbohydrate diet

CASE 4 H N, male, age fifteen years, nine months at onset. Another instance where the insulin has been lowered and kept that way for a period of nearly four years after feeding high carbohydrate low fat (Table V) As in the preceding case, we have felt that this boy was rather lean even at his most recent weight of 148 pounds He admits that very often he breaks his diet and overeats his carbohydrates by the margin of fifty grams or more, but that this does not produce glycosuria We have seen several such instances in which patients can remain sugar-free after considerable additions to their regular carbohydrate intake without an increase of insulin

CASE 5 J W, female, age at onset fourteen years At the time this patient was presented before, (1934) it was pointed out that her insulin demands were not increased after the diet was raised from 190 grams carbohydrate in 1933 to 300 grams in 1934 but since that time, two years ago, her need for insulin has diminished, although at her first visit in 1930 she was only taking forty units of insulin per day There

without reference to his diabetes—and to actually put such a diet into effect in his daily life. When such a procedure was first undertaken it was believed that two things particularly would have to be guarded against. *First*, that there would be a tendency of diabetic patients to demand a very abnormal diet for presumably, in some cases at least, an over-indulgence of food—either carbohydrate, or fat, or both—had been considered as a possible cause of the disease. *Secondly*, it was known that some diabetics had a preconceived idea of what a diabetic diet should consist of and the diet outlined was not the result of their desires but more the result of their ideas of what it should be.

Now, after these years of experience with diabetic patients approached from this point of view, we have found much to what ten years ago would have been our surprise,

that diabetic patients do not crave large amounts of sweet. It is actually difficult sometimes to persuade a diabetic patient to take more than 350 grams of carbohydrate, or more than 110 grams of protein, or more than 120 grams of fat. Occasionally a patient is met who, for a period at least, seems to crave protein, and most of them seem naturally to desire at least seventy-eighty grams of fat in the daily menu.

The evidence gathered, then, seems to point more and more to the fact that diabetic patients, as a group, tend to choose diets which we would call normal and with a ratio of carbohydrate to protein and fat of roughly 4-1-1, and as Dr Geyelin has pointed out. The patient is happier on this diet, his food desires are better satisfied, he has less tendency to shock—in other words, a more even course—and his insulin needs are rarely any higher

OVARIAN THERAPY IN GYNECOLOGY

C A ELDEN, M D, Rochester

From the Department of Obstetrics and Gynecology, University of Rochester School of Medicine and Dentistry

In the field of gynecology and obstetrics, the chemically pure hormones estrin and progesterone are available. The exact chemical formula of each is definitely known and the physiology in the human is as follows. Estrin causes definite rhythmic contractions of the uterus; is apparently antagonistic to the excretions of the anterior lobe of the pituitary gland so far as vasomotor symptoms are concerned, and is responsible for the structural changes in the endometrium and will cause bleeding if sufficient amount is given. In the normal menstrual cycle, estrin precedes progesterone and then is antagonistic to it.¹ Progesterone causes relaxation of uterine musculature,^{1,2} is antagonistic to estrin and the secretions of the posterior lobe of the pituitary gland,¹ and is responsible for the premenstrual changes in the endometrium.^{3,4}

These two hormones have been used in the treatment of certain gynecological diseases and symptoms with due regard for the known physiology. What is the value of estrin? Patients with primary amenorrhea can be made to bleed more or less cyclically, if sufficient estrin is administered in a given period of time, usually 250,000 international units in fifteen days. Bleeding with this form of

therapy is from a mid-interval type of endometrium. A second cycle of spontaneous bleeding has never been produced, therefore each subsequent cycle requires at least 250,000 international units of estrin.

Estrin can be used for the relief of menopausal symptoms, either natural or surgical. These may be entirely relieved, but when medication is stopped they return in their original frequency and severity. This hormone should be used much as morphine for the relief of pain, and when combined with the ordinary sedatives and known hygiene is a valuable adjunct in treatment. The amount used depends upon the patient. Experience has shown that 10,000 to 50,000 international units weekly are sufficient to cut down the severity of the symptoms. These observations have been confirmed on a group of castrated patients who were followed over a period of 12-18 months.⁴ During this time they bled more or less cyclically and were relieved of the hot flashes until just before bleeding started. As noted above, when medication was stopped the menopausal symptoms returned in their original frequency and severity. Therefore the etiology of this symptom complex is still unsolved.

patients are changed from the "old" types of diet to those which furnish a major portion of their total calories from carbohydrate. An added reason for selecting these cases is that they have been observed frequently and over rather long periods of time. Also, because their records as regards insulin dosage, food intake, and freedom from glycosuria are reliable.

Case 7 is interesting from three standpoints. *First*, the possibility that his relatively mild diabetes (hypoinsulinism) was preceded by what may have been a brief period of hyperinsulinism. *Second*, that after receiving high carbohydrate diet for a long period of time, his demand for insulin steadily decreased until he was able to remain sugar free on a dose as low as four units of insulin. Incidentally, this improvement in tolerance, in spite of the high carbohydrate diet, was also accompanied by a rapidly falling weight curve. *Third*, after this patient was put on a relatively high fat diet in November 1933, his tolerance steadily fell until in

1934 he was requiring greatly increased amounts of insulin without achieving a completely sugar free urine. His weight had not changed appreciably during that year. From 1934 until 1935, his weight increased by five pounds and his insulin dosage was lower concomitantly with the feeding of a higher carbohydrate lower fat diet.

The evidence presented extends and reaffirms the observations made by us and many other observers during the past ten years, viz., that the majority of diabetic patients, particularly the juvenile group, do better and feel better when normal diets adequately protected by insulin are given. As far as can be ascertained, there is no detrimental effect produced in the fundamental condition of their diabetes. With a few exceptions the insulin demand of diabetics treated with normal diet are little if any greater than the insulin demands of patients receiving the "older" type of diet. In many instances, less insulin is required.

Discussion

DR. WILLIAM S. LADD, *New York City*.—It seems hardly necessary to emphasize the significance and importance of a series of carefully conducted, continued observations such as Dr. Geyelin has reported. After all, the main purpose of the physician is to restore the patient to useful citizenship. Any method of treatment which tends to eliminate or ameliorate disease, to enable the patient to be relatively happy and content with life, to transform him from a dependent to an independent member of society, to enable youth to pursue his education and his play, and to enable an adult to work and earn his living, is, after all, meeting the test which practical therapeutics should meet and upon which its efficiency should be judged. The record of the patients which Dr. Geyelin has present is impressive.

To those of you who are not familiar with procedures in the handling of diabetic diets, it should be noted that the actual diets taken

by the patients are often not quite as rigid as the charts sometimes seem to make them, and although we use certain calculations to arrive at a diet for a given case, it is with full realization that it is probably a trial diet rather than something that may be fixed or absolute. Although Dr. Geyelin has pointed out the limits of what is considered an average diet for a great many people in many parts of the world, after all, in the individual case, the total calories of any person's diet will depend upon his energy needs and must be modified accordingly.

In considering the proportions of carbohydrate, protein, and fat in a diet, there is still another way of approaching the matter which I have used with much interest for a period of ten years or more. When a new patient presents himself, if the situation is not one of emergency, besides making the usual theoretical calculations, the patient is requested to outline a diet of his choice—

known about the disease save that it has a characteristic endometrium and no corpus luteum as noted at laparotomy. A small group of cases have been treated over a period of two years under controlled conditions.⁹ The following case history is cited as an illustration.

A single seventeen year old patient presented herself with the clinical picture of this disease. The endometrium was of a typical swiss cheese variety. She had had one curettage some six months previous to admission. Another curettage was done and the patient given $\frac{1}{4}$ - $\frac{1}{2}$ Rb U of progesterone at weekly intervals. The menstrual cycle was fairly regular for eight months, and medication was stopped for control purposes. Within six months the patient again presented herself with the typical picture of hyperplasia. Another curettage was done and progesterone therapy reinstituted. For the past eighteen months her periods have been more or less regular.

Six cases have been followed with equally good results. However an equal number of failures are reported which places the disease in the experimental phase of treatment. The work of Simpson and Burch¹⁰ with guinea pigs demonstrated that subestral amounts of estrin give the picture of hyperplasia of the endometrium, thereby indicating perhaps an imbalance between various hormones rather than an excess of estrin.

Another group of cases are those of habitual abortion for which no obvious cause can be found. It will be necessary to have a large series of cases in order to accurately evaluate the use of the hormone, or in those patients apparently successfully treated, to give no therapy should they become pregnant again. There are many factors to consider in this difficulty, and the lack of corpus luteum hormone production is only one.

Six cases with histories of two to five abortions from two to three months have had their first full term pregnancy. These patients were given one Rb U of progesterone weekly from the first missed menstrual period to the fifth lunar month. The efficacy of smaller doses remains to be satisfactorily proven.

Conclusion

Estrin, which has been supplied by Schering Corporation as Progynon-B, helps in the treatment of menopausal symptoms, senile vaginitis, and may find a place in the treatment of both degenerative and infectious atrophic arthritis. Progesterone will relieve a certain group of cases of dysmenorrhea, and will eventually take its place in the treatment of hyperplasia of the endometrium. Also, it is of benefit in carrying a pregnancy to term.

Discussion

DR. ROBERT T. FRANK, New York City.—As was to be expected of a paper emanating from such a research center as Rochester, N. Y., Dr. Elden's claims are most conservative.

His physiology is sound. I cannot vouch, from personal observation, that progesterone inhibits posterior lobe secretion although I have full proof that estrin inhibits the secretion of the anterior lobe or the pituitary. I am not convinced that the action of estrin and progesterone are antagonistic except if this interpretation is applied to the effect of the two substances on the motility of the uterus. It is true that an excess of estrin inhibits or influences the

progesterone test in the rabbit, using the glandular proliferation of the endometrium as the positive interpretation of the test.

I am not yet ready to discuss the effect of estrin on amenorrhea as so many different interpretations of the results are possible.

I fully agree on the effect produced by estrin in surgical castrates and on the neurovascular symptoms of the menopause. In the dosage which we have used, no bleeding follows.

Estrin has a limited application in the vaginitis of children and the senile. In my experience it relieves arthralgia in a certain number of cases.

Dr. Elden's results in dysmenorrhea with

Other gynecological diseases for which this hormone has been used are gonorrheal vulvovaginitis and senile vaginitis. The use of estrin for the treatment of gonorrheal vulvovaginitis in children is based on the facts that, *first*, the hormone induces cornification of the epithelium of the vagina of the rodent, *second*, the immature vaginal mucosa harbors the gonococcus in its crypts and, *third*, the disease is rarely seen in adults. Members of the Department of Pediatrics,⁵ have treated several cases with 250,000 international units of estrin over a period of eighteen days. The control cases received chemical irrigations. Cornification, as shown by smear, was produced by both means, and the gonococcus was demonstrated in those treated with estrin and not in those receiving chemical irrigations. Witherspoon⁶ has recently reported a series of cases with negative results.

Senile vaginitis, which is probably due to the lack of estrin, seems to respond well to its administration. The hormone is used in conjunction with the usually accepted form of therapy. Depending on the patient, from 10,000 to 50,000 international units weekly are necessary for relief of signs and symptoms. Treatment has proven quite satisfactory but administration must be continued from time to time since it is purely substitutional.

Outside the field of gynecology estrin is being used for the treatment of various types of arthritis. In the Department of Medicine,⁷ twenty such cases have been followed over a period of eight months with weekly doses of 10,000 to 50,000 international units. The results so far serve to emphasize the need for further investigation of estrin as an agent for the relief of symptoms, first in women with a sharp increase in joint symptoms in the premenstrual periods, and second in women of the menopausal group in whom the onset of joint pains come with the onset of menopause. It is of interest that none of the patients obtained relief with weekly doses of progesterone in the amounts used, although larger doses might prove efficacious.

Progesterone has been a distinct aid in the treatment of certain gynecological diseases such as dysmenorrhea, hyperplasia of the endometrium, and habitual abortion.

Knaus¹ has studied uterine activity during the menstrual cycle and has shown that the uterus is in a state of motility and contractility up to about the sixteenth day, due to the action of estrin. Following ovulation on the fourteenth to sixteenth day up to about twenty-four to thirty-six hours before the onset of bleeding the uterus is quiescent. Just before catamenia, uterine motility and contractility reappear. During menstruation and up to the time of ovulation the uterus reacts to pituitrin, and in the period following is refractory to pituitrin. Just before the onset of the menstrual period there is a normal hyperemia. Based on these observations it should be possible with progesterone to quiet the uterus and hence relieve dysmenorrhea. A series of forty cases were followed under controlled conditions.⁸ Patients were given intramuscular injections of 3/25-6/25 Rb U of progesterone in oil, three to five days before the expected menstrual period. If relief was obtained the patients were given injections of oil, other mucous substances or no medication. Those complaining of dysmenorrhea with this regime were included in the series of seventeen selected cases reported. Patients getting relief with sterilized oil were excluded. Of the seventeen selected cases, forty-seven per cent obtained total relief of pain, eleven per cent partial relief, and the remainder, no relief. Considering the entire group of forty patients only twenty-five per cent were relieved. It seems incredible that such small doses afforded relief. The action of progesterone may well fit into the Schroder theory, which states that the normal hyperemia causes a congestion of blood which in turn gives rise to pain. Progesterone in the small doses used may be sufficient to relax the uterus enough to allow adequate circulation with subsequent relief of pain. It may act antagonistically to the secretions of the posterior pituitary and hence keep the uterus in a state of quiescence. In selected cases it is of definite benefit, and no doubt will have to be given monthly. Experience has shown that it must be given three to five days before the period, in order to be effective, since the hormone given in oil is probably slowly absorbed.

Hyperplasia has always been and still is a bugbear of gynecology. Little is

that here the diagnosis of a basophilic tumor of the pituitary gland is relatively easy to make

While the diagnosis in cases of pituitary tumors consisting of adenomas constructed out of secreting cells is thus aided by the tell-tale evidences of the activities of their secretions, diagnosis of tumors in and around the pituitary body which interfere with its secretion or leave it unaffected, is much more difficult. This difficulty is multiplied for the neurological surgeon whose practical relations to the treatment of these tumors necessitates a much more accurate and detailed diagnosis than would suffice for the general physician or neurologist.

Of the numerous questions to be answered in the diagnosis of tumors in and around the pituitary gland exclusive of eosinophilic and basophilic adenomata, the following may be listed in logical sequence

- 1 Is there a *lesion* present, or are we dealing with an outlying example in the far-flung range of normality?
- 2 If a lesion is present, is it a *tumor* or some other disease process?
- 3 If a tumor is present, is it located within, outside of, or both within and without the sella turcica?
- 4 What is the pathological nature of the tumor?

The answers to each of these questions may be expanded into very long dissertations. We shall limit ourselves here, however, to such discussion only as will advance the solution of the problem of diagnosis

Individuals often are seen by the physician for perhaps some other cause than one connected with the pituitary gland but who have some noticeable degree of obesity, skeletal underdevelopment or malnutrition. This may be enough to lead the patient or some anxious relative, or perhaps the physician himself to wish to investigate the possible cause for that particular individual's departure from the average normal appearance. Such a person may require a much more exhaustive study than one with some more obvious disturbance. But if it is found that his general health is good, his body chemistry and metabolism, normal; if neurological examination and roentgenologic studies are all negative, then one must conclude

that this individual, who because of his appearance may belong in the outer limits of normal, still has a right to occupy a place within the bounds of normality. One may speculate as he wishes about the "endocrine balance" but the best treatment is, as a rule, no treatment at all outside of what can be accomplished by simple regulation of diet and personal hygiene

If, on the other hand, one of the above changes occurs in association with visual acuity and visual field disturbances, and changes in the appearance of the optic disks, or if these visual changes are present even without the neuro-hypophyseal signs, one must assume a local lesion to be present, and the search to be made must be directed to determine its nature

The commonest lesions in and about the pituitary region, in the order of their frequency are

Pituitary adenoma

Chromophobe

Chromophile (eosinophilic and basophilic)

"Mixed" type

Bucconeural pouch tumor

Suprasellar meningioma

Glioma of the optic chiasm

Chordoma

Angioma

Cholesteatoma

Tuberculoma

Gumma

Pituitary adenoma The chromophile adenomas, while perhaps the most interesting endocrinologically, are the easiest to diagnose and have already been discussed. The chromophobe adenomas occur about five times as frequently as the chromophile. They form masses which grow from within the substance of the anterior lobe of the pituitary body but are endocrinologically inert. As might be expected, the first symptoms they produce are due to compression of the functioning elements of the gland such as cessation of menstruation, and, in immature individuals, interruption of skeletal development. Soon, thereafter, the tumor mass grows to sufficient size to produce tension upon the sellar diaphragm, and headaches appear. It is only later on, after the neoplasm has burst through the confines of the sella that compression of the chiasm occurs which results in prim-

progesterone are not extremely convincing. He himself limits the convincing results to twenty-five percent of seventeen cases treated. His dosage of 3/25 to 6/25 of a rabbit unit is much smaller than the dosage we employ, which averages from one to five rabbit units. The few cases that we have treated were exceptionally bad, and had resisted every other form of therapy, the relief of pain, if sufficiently frequent injections are given, is striking. I have not used either of the hormones under discus-

sion in the treatment of hyperplasia. In my three cases of habitual abortions, none less than five abortions preceding, the results so far are encouraging but not conclusive, as so many variable and incalculable factors have to be considered.

DR. ELDEN—Perhaps I did not make myself clear as to the treated cases of dysmenorrhea. I actually obtained relief in forty-seven per cent of the seventeen selected cases.

DIAGNOSIS OF TUMORS IN AND AROUND THE PITUITARY GLAND

LEO M. DAVIDOFF, MD, *New York City*

The interest of the neurological surgeon in endocrinology is due primarily to the close proximity of the pituitary body to the brain. As a result of this relationship, tumors of this gland, by upward or lateral extension, may give rise to symptoms referable to the cerebrum, and thus come directly within the surgeon's field of specialized activity.

By a happy coincidence, the disease acromegaly was described by Marie in the year 1886 when Victor Horsely, through his gift as an experimental scientist, and his genius as a surgeon, had already laid the foundations for modern surgery of tumors of the brain and spinal cord. Later, Horsely himself, Aschner, and also Cushing, recognizing the relationship between the pituitary gland and acromegaly, began their experiments on animals to determine the nature of this relationship. At the same time, Horsely and Cushing were applying their rapidly improving neurosurgical technic to the tumor of the hypophysis occurring in this disease. Neither of these great masters of neurological surgery, however, limited their interest in the purely technical and mechanical side of the subject, and thus through a stimulus originating in neurological surgery, a number of most important contributions were made to endocrinology. To Dr. Cushing, although for some years now retired from active surgery, the ramification of influences exerted by the pituitary gland over the general physiology of the body has remained to this day a source of vital preoccupation. Indeed, one of his most recent contributions to science has been the establish-

ment of a syndrome resulting from a hyperactivity of the basophilic cells of the pituitary gland.
